Abstract

Testing the number of components in finite normal mixture models is a long-standing challenge because of its non-regularity. This paper studies likelihood-based testing of the number of components in normal mixture regression models with heteroscedastic components. We construct a likelihood-based test of the null hypothesis of $m_0$ components against the alternative hypothesis of $m_0 + 1$ components for any $m_0$. The null asymptotic distribution of the proposed modified EM test statistic is the maximum of $m_0$ random variables that can be easily simulated. The simulations show that the proposed test has very good finite sample size and power properties.

Key words: asymptotic distribution; modified EM test; likelihood ratio test; local MLE; normal mixture models; number of components

1 Introduction

Finite mixtures of normal distributions and regressions have been used in numerous empirical applications in diverse fields such as biological, physical, and social sciences, including economics and finance (see, e.g., Kon, 1984; Tucker, 1992; Venkataraman, 1997; Quandt and Ramsey, 1978; Kon and Jen, 1978; Conway and Deb, 2005). Mixture-of-expert models with normal component distribution (see, e.g., Jacobs et al., 1991) can also be viewed as finite mixture of normal regression models. Comprehensive theoretical accounts and examples of applications have been provided by several authors, including Lindsay (1995), Titterington et al. (1985), and McLachlan and Peel (2000).

The number of components is an important parameter in applications of finite mixture models. In economics, the number of components often represents the number of unobservable types or abilities. In other applications, the number of components signifies the number of clusters or latent classes in the data. Despite its importance, testing for the number of components in normal mixture regression models has been a long-standing unsolved problem because the standard asymptotic analysis of the likelihood ratio test (LRT) statistic breaks down due to problems such as non-identifiable parameters and the true parameter being on the boundary of the parameter space. Numerous papers have been written on the subject of the likelihood ratio test for the number of components (see, e.g., Ghosh and Sen, 1985; Chernoff and Lander, 1995; Lemdani and Pons, 1997; Chen and Chen, 2001, 2003; Chen et al., 2004; Garel, 2001, 2005), and the asymptotic distribution of the LRT statistic for general finite mixture models has been derived as a functional of the Gaussian process (Dacunha-Castelle and Gassiat, 1999; Azaïs et al., 2009; Liu and Shao, 2003; Zhu and Zhang, 2004).

In normal mixtures with heteroscedastic components, however, the asymptotic distribution of the LRT statistic remains an open question because, as discussed in Chen et al. (2012), normal mixtures have an additional undesirable mathematical property that inval-
idates key assumptions in these works. In particular, the normal density with mean $\mu$ and variance $\sigma^2$, $f(y; \mu, \sigma^2)$, has the property $\frac{\partial^2}{\partial \mu \partial \mu} f(y; \mu, \sigma^2) = 2 \frac{\partial}{\partial \sigma^2} f(y; \mu, \sigma^2)$. This leads to the loss of “strong identifiability” condition introduced by Chen (1995). As a result, neither Assumption (P1) of Dacunha-Castelle and Gassiat (1999) nor Assumption 7 of Azaïs et al. (2009) holds, and Assumption 3 of Zhu and Zhang (2004) is violated, while Corollary 4.1 of Liu and Shao (2003) does not hold in heteroscedastic normal mixtures.

This paper develops a likelihood-based testing procedure of the null hypothesis of $m_0$ components against the alternative hypothesis of $m_0 + 1$ components for a general $m_0 \geq 1$ in heteroscedastic normal mixture regression models. To this end, we introduce a new reparameterization that substantially simplifies the analysis. Under this reparameterization, the log-likelihood function is locally approximated by a quadratic function of polynomials of parameters, and a standard analysis goes through with some adjustment using the results of Andrews (1999) and Zhu and Zhang (2006), who generalize Andrews (1999). We propose a modified EM test by building on this local quadratic representation and extending the EM approach pioneered by Li et al. (2009) and Li and Chen (2010). The asymptotic null distribution of the proposed modified EM test statistic is the maximum of $m_0$ random variables, which can be easily simulated. In particular, when no regressor is present, the asymptotic null distribution is the maximum of $m_0$ chi-squared random variables with two degrees of freedom. Furthermore, the modified EM test does not suffer from the infinite Fisher information problem.

To the best of our knowledge, no likelihood-based test has yet been developed for testing the null hypothesis $H_0 : m = m_0$ with $m_0 \geq 1$ against the alternative hypothesis $H_A : m = m_0 + 1$ in normal regression mixtures. Chen and Li (2009) develop an EM test for $m_0 = 1$ in heteroscedastic normal mixtures, and Chen et al. (2012) develop an EM test for testing $H_0 : m = m_0$ against $H_A : m > m_0$ by splitting each component into two, thereby in effect testing against $H_A : m = 2m_0$, but neither Chen and Li (2009) nor Chen et al. (2012) accommodates regressors. Shen and He (2014) develop an EM test for testing
$H_0 : m_0 = 1$ in normal regression mixtures with covariate-dependent mixing proportions, in which the Fisher information matrix is regular. The test of Shen and He (2014) has a simpler limiting distribution, but its power is low when the mixing proportion does not depend on covariates. Our test is designed for such models, and as such, our test and theirs are mutually complementary.

Model selection procedures have been proposed for estimating the number of components in mixture models (see, for example, Henna, 1985; Lindsay and Roeder, 1992; Windham and Cutler, 1992; Roeder, 1994; Chen and Kalbfleisch, 1996; Keribin, 2000; James et al., 2001; Miloslavsky and van der Laan, 2003; Woo and Sriram, 2006; Chen and Khalili, 2008). As discussed in Chen et al. (2012), while model selection procedures seek to find a parsimonious model that adequately describes the observed data, the number of components is often linked to scientific propositions, and a hypothesis test can be used to check their validity.

The remainder of this paper is organized as follows. Section 2 introduces finite normal mixture regression models. Sections 3 and 4 establish the local quadratic approximation in testing the null hypothesis of $m_0$ components against the alternative of $m_0 + 1$ components. Section 5 introduces the modified EM test. Section 6 reports the simulation results, and empirical examples are provided in Section 7. The supplementary appendix contains proofs, auxiliary results, and additional empirical examples. All limits below are taken as $n \to \infty$, unless stated otherwise. Let $\equiv$ denote “equals by definition.” For a $k \times 1$ vector $a$ and a function $f(a)$, let $\nabla_a f(a)$ denote the $k \times 1$ vector of the derivative $(\partial/\partial a) f(a)$, and let $\nabla_{aa^\top} f(a)$ denote the $k \times k$ vector of the derivative $(\partial/\partial a \partial a^\top) f(a)$.

## 2 Finite normal mixture regression models

Denote the density of a normal distribution with mean $\mu + x^\top \beta + z^\top \gamma$ and variance $\sigma^2$ by

$$f(y|x, z; \gamma, \theta, \sigma^2) := \frac{1}{\sigma} \phi \left( \frac{y - \mu - x^\top \beta - z^\top \gamma}{\sigma} \right).$$
where $\mathbf{\theta} := (\mu, \mathbf{\beta}^\top) \in (q+1) \times 1$, $\mu$ is scalar, $\mathbf{x} = (x_1, \ldots, x_q)^\top$ and $\mathbf{\beta}$ are $q \times 1$, $\mathbf{z}$ and $\mathbf{\gamma}$ are $p \times 1$, and $\phi(t) := (2\pi)^{-1/2} \exp(-t^2/2)$. Let $\Theta_{\mathbf{\gamma}} \subset \mathbb{R}^p$, $\Theta_{\mathbf{\theta}} = \Theta_{\mu} \times \Theta_{\mathbf{\beta}} \subset \mathbb{R}^{q+1}$, and $\Theta_{\sigma} \subset \mathbb{R}_{++}$ denote the space of $\mathbf{\gamma}$, $\mathbf{\theta}$, and $\sigma^2$, respectively. We consider an $m$-component finite mixture density:

$$f_m(y|x, z; \vartheta_m) := \sum_{j=1}^{m} \alpha_j f(y|x, z; \gamma, \theta_j, \sigma_j^2), \quad (1)$$

where $\vartheta_m := (\alpha^\top, \mathbf{\gamma}^\top, \theta_1^\top, \ldots, \theta_m^\top, \sigma_1^2, \ldots, \sigma_m^2)^\top$ with $\alpha := (\alpha_1, \ldots, \alpha_{m-1})^\top$, and $\alpha_m$ being determined by $\alpha_m := 1 - \sum_{j=1}^{m-1} \alpha_j$. $\theta_j$ and $\sigma_j^2$ are mixing parameters that characterize the $j$-th component, $\gamma$ is a structural parameter that is common to all the components, and $\alpha_j$s are mixing probabilities. Define the set of admissible values of $\alpha$ by $\Theta_{\alpha} := \{\alpha : \alpha_j \geq 0, \sum_{j=1}^{m-1} \alpha_j \in [0, 1]\}$, and let the space of $\vartheta_m$ be $\Theta_{\vartheta_m} := \Theta_{\alpha} \times \Theta_{\gamma} \times \Theta_{\theta_1} \times \Theta_{\sigma_1} \times \Theta_{\theta_2} \times \Theta_{\sigma_2}$.

We define the number of components $m$ by the smallest number such that the data density admits the representation (1). Our objective is to test

$$H_0 : m = m_0 \quad \text{against} \quad H_A : m = m_0 + 1.$$  

3 Local quadratic approximation for testing $H_0 : m = 1$ against $H_A : m = 2$

In this section, we develop a local quadratic approximation for testing the null hypothesis $H_0 : m = 1$ against $H_A : m = 2$ when the data are from $H_0$. We consider a random sample of $n$ independent observations $\{Y_i, X_i, Z_i\}_{i=1}^{n}$ from the true one-component density $f(y|x, z; \gamma^*, \theta^*, \sigma^{2*})$. Here, the superscript * denotes the true population value. Let a two-component mixture density function with $\vartheta_2 = (\alpha, \mathbf{\gamma}^\top, \theta_1, \theta_2, \sigma_1^2, \sigma_2^2)^\top \in \Theta_{\vartheta_2}$ be

$$f_2(y|x, z; \vartheta_2) := \alpha f(y|x, z; \gamma, \theta_1, \sigma_1^2) + (1 - \alpha) f(y|x, z; \gamma, \theta_2, \sigma_2^2). \quad (2)$$
The model (2) yields the true density \( f(y|x, z; \gamma^*, \theta^*, \sigma^2) \) if \( \theta_2 \) lies in the set \( \Theta_2^\star := \{ \theta_2 \in \Theta_{\theta_2} : (\theta_1, \sigma_1^2) = (\theta_2, \sigma_2^2) = (\theta^*, \sigma^2), \gamma = \gamma^* \} \) or \( \{ \alpha(1 - \alpha) = 0, \gamma = \gamma^* \} \).

We partition the null hypothesis \( H_0 : m = 1 \) into two as follows:

\[
H_{01} : (\theta_1, \sigma_1^2) = (\theta_2, \sigma_2^2) \quad \text{and} \quad H_{02} : \alpha(1 - \alpha) = 0.
\]

The regularity conditions for a standard asymptotic analysis fails in finite mixture models because (i) under \( H_{01} \), \( \alpha \) is not identified, and the Fisher information matrix for the other parameters becomes singular; (ii) under \( H_{02} \), \( \alpha \) is on the boundary of the parameter space, and either \( \theta_1 \) or \( \theta_2 \) is not identified.

In addition to the failure of regularity conditions that is common to all finite mixture models, the normal mixture model (2) has additional undesirable mathematical properties, as discussed in Chen and Li (2009): (a) The Fisher information for testing \( H_{02} \) is not finite unless the range of \( \sigma_1^2/\sigma_2^2 \) is restricted. (b) The derivatives of \( f_2(y|x, z; \theta_2) \) of different orders are linearly dependent because \( \nabla_{\mu\mu} f(y|x, z; \theta, \sigma^2) = 2\nabla_{\sigma^2} f(y|x, z; \gamma, \theta, \sigma^2) \) (loss of strong identifiability). (c) The log-likelihood function is unbounded and the maximum likelihood estimate fails to exist (Hartigan, 1985; Kiefer and Wolfowitz, 1956).

In view of problem (a), we focus on testing \( H_{01} : (\theta_1, \sigma_1^2) = (\theta_2, \sigma_2^2) \) in the following. We handle problem (c) by considering a maximum likelihood estimator (MLE) in the constrained parameter space \( \Theta_{\theta_2}(\epsilon_\sigma) := \{ \theta_2 \in \Theta_{\theta_2} : \min \{ \sigma_1/\sigma_2, \sigma_2/\sigma_1 \} \geq \epsilon_\sigma \} \) for some \( \epsilon_\sigma > 0 \), as in Hathaway (1985). Let \( \hat{\theta}_2 \) denote the constrained MLE that maximizes \( L_n(\theta_2) := \sum_{i=1}^n f_2(Y_i|X_i, Z_i; \theta_2) \) under the constraint \( \theta_2 \in \Theta_{\theta_2}(\epsilon_\sigma) \). The following proposition shows the consistency of \( \hat{\theta}_2 \) by extending the result of Hathaway (1985) to accommodate covariates \( X \) and \( Z \).

**Assumption 1.** \( X \) and \( Z \) have finite second moment, and \( \Pr(X_i^\top \beta_j + Z_i^\top \gamma \neq X_i^\top \beta_j^* + Z_i^\top \gamma^*) > 0 \) for any \( (\beta_j^\top, \gamma^\top) \neq ((\beta_j^*)^\top, (\gamma^*)^\top) \) and \( j = 1, \ldots, m \).
Proposition 1. Suppose that Assumption 1 holds. Then, under the null hypothesis $H_0 : m = 1$, $\inf_{\vartheta_2 \in \Theta_2^*} || \hat{\vartheta}_2 - \vartheta_2 || \to 0$ almost surely.

Let $l(y|x, z; \vartheta_2) := \ln (\alpha f(y|x, z; \theta_1, \sigma_1^2) + (1 - \alpha) f(y|x, z; \gamma, \theta_2, \sigma_2^2))$ denote the log-density of the two-component model. For any $\bar{\vartheta}_2$ such that $(\theta_1, \sigma_1^2) = (\theta_2, \sigma_2^2)$, the derivatives of the log-density are linearly dependent as

$$
\nabla_{\theta_1} l(y|x, z; \bar{\vartheta}_2) = \frac{\alpha}{1 - \alpha} \nabla_{\theta_2} l(y|x, z; \bar{\vartheta}_2), \quad \nabla_{\sigma_1^2} l(y|x, z; \bar{\vartheta}_2) = \frac{\alpha}{1 - \alpha} \nabla_{\sigma_2^2} l(y|x, z; \bar{\vartheta}_2),
$$

(3)

$$
\nabla_{\mu_j \mu_j} l(y|x, z; \bar{\vartheta}_2) = 2 \nabla_{\sigma_j^2} l(y|x, z; \bar{\vartheta}_2) \text{ for } j = 1, 2.
$$

(4)

Consequently, the Fisher information matrix is degenerate, which invalidates the standard second-order quadratic approximation analysis. In particular, dependence (4) causes substantial difficulties in existing literature.

We analyze the LRT statistic for testing $H_{01} : (\theta_1, \sigma_1) = (\theta_2, \sigma_2)$ by developing a higher-order approximation of the log-likelihood function that can be expressed in a quadratic form, when $\alpha \in (0, 1)$, through a judiciously designed reparameterization by extending the result of Rotnitzky et al. (2000). Consider the following one-to-one mapping between $(\theta_1, \theta_2, \sigma_1^2, \sigma_2^2) = (\mu_1, \beta_1, \mu_2, \beta_2, \sigma_1^2, \sigma_2^2)$ and the reparameterized parameter $(\lambda_\theta, \nu_\theta, \lambda_\sigma, \nu_\sigma) = (\lambda_\mu, \lambda_\beta, \nu_\mu, \nu_\beta, \lambda_\sigma, \nu_\sigma)$:

\[
\begin{pmatrix}
\theta_1 \\
\theta_2 \\
\sigma_1^2 \\
\sigma_2^2
\end{pmatrix}
= \begin{pmatrix}
\nu_\theta + (1 - \alpha) \lambda_\theta \\
\nu_\theta - \alpha \lambda_\theta \\
\nu_\sigma + (1 - \alpha) (2 \lambda_\sigma + C_1 \lambda_\mu^2) \\
\nu_\sigma - \alpha (2 \lambda_\sigma + C_2 \lambda_\mu^2)
\end{pmatrix},
\]

(5)

where $\nu_\theta = (\nu_\mu, \nu_\beta)^\top$, $\lambda_\theta = (\lambda_\mu, \lambda_\beta)^\top$, $C_1 := -(1/3)(1 + \alpha)$, and $C_2 := (1/3)(2 - \alpha)$.
Collect the reparameterized parameters, except for $\alpha$, into one vector $\psi_\alpha$ defined as

$$\psi_\alpha := (\gamma^T, \nu_\theta^T, \nu_\sigma, \lambda_\theta^T, \lambda_\sigma^T)^T = (\gamma^T, \nu_\mu, \nu_\beta^T, \nu_\sigma, \lambda_\mu, \lambda_\beta, \lambda_\sigma)^T \in \Theta_{\psi_\alpha}. \quad (6)$$

In the reparameterized model, the null hypothesis of $H_0: (\theta_1^T, \sigma_1^2) = (\theta_2^T, \sigma_2^2)$ is written as $H_0: (\lambda_\theta^T, \lambda_\sigma) = (0, \ldots, 0)$, and the density and its logarithm are given by

$$g(y|x, z; \psi_\alpha, \alpha) = \alpha f(y|x, z; \gamma, \nu_\theta + (1 - \alpha)\lambda_\theta, \nu_\sigma + (1 - \alpha)(2\lambda_\sigma + C_1\lambda_\beta^2))$$

$$+ (1 - \alpha)f(y|x, z; \gamma, \nu_\theta - \alpha\lambda_\theta, \nu_\sigma - \alpha(2\lambda_\sigma + C_2\lambda_\beta^2)),$$

and $l(y|x, z; \psi_\alpha, \alpha) = \ln[g(y|x, z; \psi_\alpha, \alpha)]$.

Partition $\psi_\alpha$ as $\psi_\alpha = (\eta^T, \lambda^T)^T$, where $\eta := (\gamma^T, \nu_\theta^T, \nu_\sigma)^T \in \Theta_\eta$ and $\lambda := (\lambda_\theta, \lambda_\sigma)^T \in \Theta_\lambda$. Denote the true values of $\eta$, $\lambda$, and $\psi$ by $\eta^* := ((\gamma^*)^T, (\theta^*)^T, \sigma^{*2})^T$, $\lambda^* := (0, \ldots, 0)^T$, and $\psi^*_\alpha = ((\eta^*)^T, 0, \ldots, 0)^T$, respectively. The first derivative of $(7)$ w.r.t. $\eta$ under $\psi_\alpha = \psi^*_\alpha$ is identical to the score of the one-component model:

$$\nabla_\eta l(y|x, z; \psi^*_\alpha, \alpha) = \frac{\nabla_{(\gamma^T, \theta^T, \sigma^{*2})^T} f(y|x, z; \gamma^*, \theta^*, \sigma^{*2})}{f(y|x, z; \gamma^*, \theta^*, \sigma^{*2})}.$$ 

(8)

On the other hand, Proposition C in the supplementary appendix shows that the first, second, and third derivatives of the reparameterized log-density $(7)$ w.r.t. $\lambda_\mu$, and the first derivative w.r.t. $\lambda_\sigma$ or $\lambda_\beta$ become zero when evaluated at $\psi_\alpha = \psi^*_\alpha$:

$$\nabla_{\lambda_\mu} l(y|x, z; \psi^*_\alpha, \alpha) = 0, \quad \nabla_{\lambda_\sigma}^2 l(y|x, z; \psi^*_\alpha, \alpha) = 0, \quad \nabla_{\lambda_\beta}^3 l(y|x, z; \psi^*_\alpha, \alpha) = 0,$$

$$\nabla_{\lambda_\sigma} l(y|x, z; \psi^*_\alpha, \alpha) = 0, \quad \nabla_{\lambda_\beta} l(y|x, z; \psi^*_\alpha, \alpha) = 0.$$ 

(9)

Consequently, the information on $\lambda_\mu$, $\lambda_\sigma$, and $\lambda_\beta$ is provided by the derivatives w.r.t. $\lambda_\mu^4$, $\lambda_\sigma^2$, $\lambda_\mu\lambda_\sigma$, $\lambda_\beta\lambda_\mu$, $\lambda_\beta\lambda_\sigma$, and vech$(\lambda_\beta^T\lambda_\beta^-1)$. For $\lambda_\beta := (\lambda_1, \ldots, \lambda_q)^T \in \mathbb{R}^q$, collect the elements of vech$(\lambda_\beta\lambda_\beta^-1)$ into a $q(q+1)/2 \times 1$ vector as $v_\beta(\lambda_\beta) = (v_{11}, \ldots, v_{qq}, v_{12}, \ldots, v_{1q}, v_{23}, \ldots, v_{2q}, \ldots, v_{q-1,q})^T := (\lambda_1^2, \ldots, \lambda_q^2, \lambda_1\lambda_2, \ldots, \lambda_1\lambda_q, \lambda_2\lambda_3, \ldots, \lambda_2\lambda_q, \ldots, \lambda_{q-1}\lambda_q)^T$. Collect the relevant parameters.
\[ t_n(\psi, \alpha) := (t_{\eta n}, t_{\lambda n})^\top, \]  

(10)

where \( t_{\eta n} := n^{1/2}(\eta - \eta^*) \) and

\[
\begin{pmatrix}
t_{\mu n} \\
t_{\lambda n} \\
t_{\beta n}
\end{pmatrix}
= 
\begin{pmatrix}
\frac{1}{2} \alpha (1 - \alpha) 6 \lambda \mu \\
\frac{1}{2} \alpha (1 - \alpha) 2 \lambda \beta \\
\frac{1}{2} \alpha (1 - \alpha) \nu \beta
\end{pmatrix},
\]

(11)

with \( b(\alpha) := -(2/3)(\alpha^2 - \alpha + 1) < 0 \).

Let \( L_n(\psi, \alpha) := \sum_{i=1}^n l(Y_i|X_i, Z_i; \psi, \alpha) \) denote the reparameterized log-likelihood function. Define the normalized score as

\[
S_n := n^{-1/2} \sum_{i=1}^n s_i \text{ and } I_n := n^{-1} \sum_{i=1}^n s_i s_i^\top,
\]

where \( s_i := (s_{\eta i}^\top, s_{\lambda i}^\top, s_{\mu \alpha i}^\top, s_{\lambda \beta i}^\top)^\top \) and

\[
\begin{pmatrix}
H_{i1}^s Z_i \\
H_{i1}^{3s} \\
H_{i1}^{4s} X_i \\
H_{i1}^{1s} X_i \\
H_{i1}^{2s} X_i
\end{pmatrix}, \quad \begin{pmatrix}
H_{i1}^{s} \\
H_{i1}^{3s} \\
H_{i1}^{4s} \\
H_{i1}^{1s} \\
H_{i1}^{2s}
\end{pmatrix}, \quad \begin{pmatrix}
H_i^{2s}(X_{1i})^2 \\
:\ \\
H_i^{2s}(X_{qi})^2 \\
2H_i^{2s}X_{1i}X_{2i} \\
:\ \\
2H_i^{2s}X_{q-1,i}X_{qi}
\end{pmatrix},
\]

(12)

and \( H_i^{ks} := H^k \left( (Y_i - \mu^* - X_i^\top \beta^* - Z_i^\top \gamma^*)/\sigma^* \right) / ((\sigma^*)^{k!}) \), where \( H^k(z) \) is the Hermite polynomial of order \( k \) given by \( H^1(z) = z, H^2(z) = z^2 - 1, H^3(z) = z^3 - 3z, \) and \( H^4(z) = z^4 - 6z^2 + 3 \).

With these notations, expanding \( L_n(\psi, \alpha) \) nine times around \( (\psi^*, \alpha) \), we can write
\[ L_n(\psi_\alpha, \alpha) - L_n(\psi_\alpha^*, \alpha) \] as a quadratic function of \( t_n(\psi_\alpha, \alpha) \) as

\[ L_n(\psi_\alpha, \alpha) - L_n(\psi_\alpha^*, \alpha) = t_n(\psi_\alpha, \alpha)^T S_n - \frac{1}{2} t_n(\psi_\alpha, \alpha)^T \mathbf{I}_n t_n(\psi_\alpha, \alpha) + R_n(\psi_\alpha, \alpha). \quad (13) \]

Define the variance of the score as \( \mathbf{I} := E[s_i s_i^T] = E[\mathbf{I}_n] \).

**Assumption 2.** (a) \( X \) and \( Z \) have finite ninth moments. (b) \( E[U_1 U_1^T] \) and \( E[U_2 U_2^T] \) are nonsingular, where \( U_1 = (1, X^T, Z^T)^T \) and \( U_2 = (1, X^T, X_1^2, X_2^2, 2X_1X_2, \ldots, 2X_{q-1}X_q)^T \).

**Proposition 2.** Suppose that Assumptions 1 and 2 hold. Then, under the null hypothesis \( H_0 : m = 1, \) for \( \alpha \in (0, 1) \) and \( \epsilon_\sigma \in (0, 1) \), we have (a) for any \( \delta > 0, \)

\[ \lim_{n \to \infty} \text{Pr}(\sup_{\alpha \in (0, 1)} |R_n(\psi_\alpha, \alpha)| > \delta(1 + ||t_n(\psi_\alpha, \alpha)||^2)) \to 0 \text{ as } \kappa \to 0, \]

(b) \( S_n \to_d S \sim N(0, \mathbf{I}) \), and (c) \( \mathbf{I}_n \to_p \mathbf{I} \), where \( \mathbf{I} \) is nonsingular.

Let \( \hat{\psi}_\alpha := \arg\max_{\psi_\alpha \in \Theta_\psi(\epsilon_\sigma)} L_n(\psi_\alpha, \alpha) \) denote the (constrained) MLE of \( \psi_\alpha \), where \( \Theta_\psi(\epsilon_\sigma) \) is defined so that the value of \( \vartheta_2 \) implied by \( \psi_\alpha \) is in \( \Theta_\vartheta_2(\epsilon_\sigma) \). Let \( (\hat{\gamma}_0, \hat{\theta}_0, \hat{\sigma}_0^2) \) denote the one-component MLE that maximizes the one-component log-likelihood function

\[ L_{0,n}(\gamma, \theta, \sigma^2) := \sum_{i=1}^n \ln f(Y_i|X_i, Z_i; \gamma, \theta, \sigma^2). \]

Define the LRT statistic for testing \( H_{01} \) as

\[ LR_n(\epsilon_1) := \max_{\alpha \in [\epsilon_1, 1-\epsilon_1]} \{ L_n(\psi_\alpha, \alpha) - L_{0,n}(\hat{\gamma}_0, \hat{\theta}_0, \hat{\sigma}_0^2) \} \]

with \( \epsilon_1 \in (0, 1/2) \).

Let \( \Lambda_n \) be the set of admissible values of \( t_n(\psi_\alpha, \alpha) = (t_{\mu \sigma}^T, t_{\mu \beta}^T, t_{\beta \sigma}^T, t_{\beta \beta}^T)^T \) defined in (10). The asymptotic null distribution of \( LR_n(\epsilon_1) \) is characterized by the supremum of the quadratic-form representation of the log-likelihood ratio under the constraint implied by the limit of \( \Lambda_n \) as \( n \to \infty \). As shown in the proof of Proposition 3, the limit of \( \Lambda_n \) is given by the union of \( \Lambda^1_\Lambda \) and \( \Lambda^2_\Lambda \), where \( q_\lambda := 2 + 2q + q(q + 1)/2 \) and

\[ \Lambda^1_\Lambda := \{ t_\lambda = (t_{\mu \sigma}, t_{\mu \beta}, t_{\beta \sigma}^T, t_{\beta \beta}^T)^T \in \mathbb{R}^{q_{\lambda}} : (t_{\mu \sigma}, t_{\mu \beta}, t_{\beta \sigma}^T, t_{\beta \beta}^T)^T \in \mathbb{R} \times \mathbb{R}^\times \times \mathbb{R}^q, t_{\beta \sigma} = t_{\beta \beta} = 0 \} \text{ and } \]

\[ \Lambda^2_\Lambda := \{ t_\lambda = (t_{\mu \sigma}, t_{\mu \beta}, t_{\beta \sigma}^T, t_{\beta \beta}^T)^T \in \mathbb{R}^{q_{\lambda}} : t_{\mu \sigma} = 6\lambda_{\mu} \lambda_{\sigma}, t_{\mu \beta} = 12\lambda_{\sigma} \lambda_{\mu}, t_{\beta \sigma} = 6\lambda_{\beta} \lambda_{\sigma}, t_{\beta \beta} = \beta(\lambda_{\beta}) \text{ for some } \lambda \in \mathbb{R}^{2+q} \}. \quad (14) \]
Partition $S$ and $W = \mathcal{I}^{-1}S$ as $S = (S_\eta, S_\lambda)^\top$, $W = (W_\eta^\top, W_\lambda^\top)$, where $S_\eta$ and $W_\eta$ are $(p+q+2) \times 1$, and $S_\lambda$ and $W_\lambda$ are $q_\lambda \times 1$. Define $\mathcal{I}_\eta := E(S_\eta S_\eta^\top)$, $\mathcal{I}_{\eta\eta} := E(S_\eta S_\eta^\top)$, $\mathcal{I}_{\eta\lambda} := \mathcal{I}_{\eta\lambda}^\top$, and $\mathcal{I}_\lambda := E(S_\lambda S_\lambda^\top)$. Note that $W_\lambda = \mathcal{I}_\lambda^{-1}S_\lambda\eta$, where $S_{\lambda\eta} := S_\lambda - \mathcal{I}_{\lambda\eta}\mathcal{I}_{\eta\lambda}^{-1}S_\eta$ and $\mathcal{I}_{\lambda\eta} := \mathcal{I}_\lambda - \mathcal{I}_{\lambda\eta}\mathcal{I}_{\eta\lambda}^{-1}\mathcal{I}_\lambda\eta$. For $j = 1, 2$, define $t_\lambda^j$ by

$$
 r_\lambda(t_\lambda^j) = \inf_{t_\lambda \in \Lambda_\lambda^j} r_\lambda(t_\lambda), \quad r_\lambda(t_\lambda) := (t_\lambda - W_\lambda)^\top \mathcal{I}_{\lambda\eta}(t_\lambda - W_\lambda). \tag{15}
$$

The following proposition establishes the asymptotic null distribution of the LRT statistic. When the model does not have a conditioning variable $X$, the set of admissible values of $t_{\lambda n}$ converges to $\mathbb{R}^2$, and $LR_n(\epsilon_1)$ converges to $\chi^2(2)$ in distribution.

**Proposition 3.** Suppose that Assumptions 1 and 2 hold, $\epsilon_\sigma \in (0, 1)$, and $\epsilon_1 \in (0, 1/2)$. Then, under the null hypothesis $H_0 : m = 1$, (a) $t_n(\hat{\psi}_\alpha, \alpha) = O_p(1)$ for any $\alpha \in (0, 1)$, (b) $LR_n(\epsilon_1) \to_d \chi^2(2)$ if the model does not have a conditioning variable $X$, and (c) $LR_n(\epsilon_1) \to_d \max\{(t_\lambda^1)^\top I_{\lambda\eta} t_\lambda^1, (t_\lambda^2)^\top I_{\lambda\eta} t_\lambda^2\}$.

Under the alternative $H_A : m = 2$, the constrained MLE $\hat{\psi} := \arg \max_{\alpha \in [\epsilon_1, 1-\epsilon_1]} L_n(\hat{\psi}_\alpha, \alpha)$ is consistent if the true parameter value $\theta_2^*$ lies in the set $\Theta_{\theta_2}(\epsilon_\sigma, \epsilon_1) := \{\theta_2 \in \Theta_{\theta_2} : \min\{\sigma_1/\sigma_2, \sigma_2/\sigma_1\} \geq \epsilon_\sigma \text{ and } \alpha \in [\epsilon_1, 1-\epsilon_1]\}$ that involve ad hoc constants $\epsilon_\sigma$ and $\epsilon_1$. If $\theta_2^*$ does not lie in $\Theta_{\theta_2}(\epsilon_\sigma, \epsilon_1)$, the constrained MLE converges to the value of $\psi_\alpha$ that minimizes the Kullback–Leibler divergence between the true density $f_2(y|x, z; \theta_2)$ and the class of density $\{f_2(y|x, z; \theta_2) : \theta_2 \in \Theta_{\theta_2}(\epsilon_\sigma, \epsilon_1)\}$ (White, 1982). Consequently, $LR_n(\epsilon_1)$ may have reduced power against alternatives in which $(\alpha, \sigma_1, \sigma_2)$ does not satisfy the constraint $\Theta_{\theta_2}(\epsilon_\sigma, \epsilon_1)$.

Liu and Shao (2003) analyze the LRT statistic of mixture models. Their Corollary 4.1 with $(m, t) = (2, 2)$ corresponds to testing the null hypothesis $H_{01}^\ast : \theta_1 = \theta_2 = \theta^\ast$. According to their Corollary 4.1, the generalized score function of the LRT statistic for testing $H_{01}^\ast$ is obtained by expanding the log-likelihood function twice. Our Proposition 3 and its proof show that in heteroscedastic normal mixture models, the likelihood function needs to be
expanded further.

When \( X \) contains dummy variables that take value 0 or 1, Assumption 2(b) fails because a dummy variable and its square in \( U_2 \) are perfectly correlated with each other. The following proposition handles such cases. Define \( U_2^0 := (X^\top, X_1^2, \ldots, X_q^2, 2X_1X_2, \ldots, 2X_{q-1}X_q)^\top \), so that \( U_2 = (1, (U_2^0)^\top)^\top \), and let \( q_2 := \dim(U_2^0) = q + q(q + 1)/2 \).

**Assumption 3.** (a) There exists a \( d \times q_2^2 \) matrix \( B \) of rank \( d \) such that \( BU_2^0 = 0 \). (b) \( E[U_1U_1^\top] \) and \( E[B^\perp U_2^0(B^\perp U_2^0)^\top] \) are nonsingular, where \( B^\perp \) is a \((q_2 - d) \times q_2^2 \) matrix whose rows are the basis of the orthogonal complement of the row space of \( B \).

**Proposition 4.** Suppose that Assumptions 1, 2(a), and 3 hold. Then, \( LR_n(\epsilon_1) \to_d \max\{(t^B_\lambda)^\top I_\lambda^B t^B_\lambda, (t^B_\lambda)^\top I_\lambda^B t^B_\lambda, (t^B_\lambda)^\top I_\lambda^B t^B_\lambda\} \), where the definitions of \( t^B_\lambda \) and \( I_\lambda^B \) are provided in the proof in the supplementary appendix.

4 Local quadratic approximation for testing \( H_0 : m = m_0 \) against \( H_A : m = m_0 + 1 \) for \( m_0 \geq 2 \)

In this section, we develop a local quadratic approximation for testing the null hypothesis of \( m_0 \) components against the alternative of \( m_0 + 1 \) components for general \( m_0 \geq 2 \). We consider a random sample of \( n \) independent observations \( \{Y_i, X_i, Z_i\}_{i=1}^n \) generated from the \( m_0 \)-component normal mixture density with the true parameter value \( \vartheta^*_{m_0} := (\alpha_1^*, \ldots, \alpha_{m_0-1}^*, (\gamma^*)^\top, (\theta_1^*)^\top, \ldots, (\theta_m^*)^\top, \sigma_1^{2*}, \ldots, \sigma_m^{2*})^\top \) with \( \alpha_j^* > 0 \):

\[
f_{m_0}(y|x, z; \vartheta^*_{m_0}) := \sum_{j=1}^{m_0} \alpha_j^* f(y|x, z; \gamma^*, \theta_j^*, \sigma_j^{2*}). \tag{16}
\]
We assume \((\theta_1^*, \sigma_1^{2*}) < \ldots < (\theta_{m_0}^*, \sigma_{m_0}^{2*})\) for identification. Let the density of an \((m_0 + 1)\)-component mixture model be

\[
    f_{m_0+1}(y|x, z; \vartheta_{m_0+1}) := \sum_{j=1}^{m_0+1} \alpha_j f(y|x, z; \gamma, \theta_j, \sigma_j^2),
\]

(17)

where \(\vartheta_{m_0+1} := (\alpha_1, \ldots, \alpha_{m_0}, \gamma^\top, \theta_1^\top, \ldots, \theta_{m_0+1}^\top, \sigma_1^2, \ldots, \sigma_{m_0+1}^2)^\top\). Similar to the case of the test of homogeneity, we partition the null hypothesis into two as \(H_0 = H_{01} \cup H_{02}\), where \(H_{01} := \cup_{h=1}^{m_0} H_{0,1h}\) and \(H_{02} := \cup_{h=1}^{m_0+1} H_{0,2h}\) with

\[
    H_{0,1h} : (\theta_1, \sigma_1^2) < \ldots < (\theta_h, \sigma_h^2) = (\theta_{h+1}, \sigma_{h+1}^2) < \ldots < (\theta_{m_0+1}, \sigma_{m_0+1}^2) \quad \text{and} \quad H_{0,2h} : \alpha_h = 0.
\]

The inequality constraints are imposed on \((\theta_j, \sigma_j^2)\) for identification.

We focus on testing \(H_{01}\) because (i) the LRT statistic for testing \(H_{02}\) has infinite Fisher information unless a stringent restriction is imposed on the admissible values of \(\sigma_j^2\), and (ii) implementing the LRT for \(H_{02}\) is practically difficult because the asymptotic null distribution depends on the functional of a multidimensional Gaussian process. Define the set of values of \(\vartheta_{m_0+1}\) that yields the true density (16) as \(\Upsilon^* := \{\vartheta_{m_0+1} : f_{m_0+1}(Y|X, Z; \vartheta_{m_0+1}) = f_m(Y|X, Z; \vartheta_{m_0})\}\) with probability one. Under \(H_{0,1h}\), the \((m_0 + 1)\)-component model (17) generates the true \(m_0\)-component density (16) when \((\theta_h, \sigma_h^2) = (\theta_{h+1}, \sigma_{h+1}^2) = (\theta_j^*, \sigma_j^{2*})\). Define the subset of \(\Upsilon^*\) corresponding to \(H_{0,1h}\) as

\[
    \Upsilon_{1h}^* := \{\vartheta_{m_0+1} \in \Theta_{\vartheta_{m_0+1}} : \alpha_j > 0 \text{ for } j = 1, \ldots, m_0 + 1; \quad \alpha_h + \alpha_{h+1} = \alpha_h^* \quad \text{and} \quad
    (\theta_h, \sigma_h^2) = (\theta_{h+1}, \sigma_{h+1}^2) = (\theta_j^*, \sigma_j^{2*}); \quad \alpha_j = \alpha_j^* \quad \text{and} \quad (\theta_j, \sigma_j^2) = (\theta_j^*, \sigma_j^{2*}) \quad \text{for } j < h;
\]

\[
    \alpha_j = \alpha_{j-1}^* \quad \text{and} \quad (\theta_j, \sigma_j^2) = (\theta_{j-1}^*, \sigma_{j-1}^{2*}) \quad \text{for } j > h + 1; \quad \gamma = \gamma^*};
\]

and define \(\Upsilon_1^* := \Upsilon_{11}^* \cup \cdots \cup \Upsilon_{1m_0}^*\).

Similar to Section 3, we consider the MLE in the constrained parameter space \(\Theta_{\vartheta_m}(\epsilon_\sigma) :=\)
\{\theta_m \in \Theta_{\theta_m} : \min_{j,k} \{\sigma_j/\sigma_k\} \geq \epsilon_\sigma\} for some \epsilon_\sigma > 0. For \epsilon_1 \in (0, 1/2), let \Theta_{\theta_{m_0+1}}(\epsilon_\sigma, \epsilon_1) be a subset of \Theta_{\theta_{m_0+1}}(\epsilon_\sigma) such that \alpha_j \in [\epsilon_1, 1-\epsilon_1] for \ j = 1, \ldots, m_0+1, and define the LRT statistic for testing \(H_{01}\) as

\[
LR_{n|f}^{m_0}(\epsilon_1) := \max_{\theta_{m_0+1} \in \Theta_{\theta_{m_0+1}}(\epsilon_\sigma, \epsilon_1)} 2\{L_n(\theta_{m_0+1}) - L_{0n}(\hat{\theta}_{m_0})\},
\]

where

\[
L_n(\theta_{m_0+1}) := \sum_{i=1}^n \ln f_{m_0+1}(Y_i|X_i; Z_i; \theta_{m_0+1}), \quad L_{0n}(\theta_{m_0}) := \sum_{i=1}^n \ln f_{m_0}(Y_i|X_i; Z_i; \theta_{m_0}),
\]

and \(\hat{\theta}_{m_0} := \arg \max_{\theta_{m_0} \in \Theta_{\theta_{m_0}(\epsilon_\sigma)}} L_{0n}(\theta_{m_0})\). Collect the score vector for testing \(H_{011, \ldots, H_{01m_0}}\) into one vector as

\[
\tilde{s}_i := \begin{pmatrix} s_{\eta_i} \\ s_{\lambda_i} \end{pmatrix}, \quad \text{where} \quad \tilde{s}_{\eta_i} := \begin{pmatrix} s_{\alpha_i} \\ s_{\gamma_i} \\ s_{(\theta, \sigma)i} \end{pmatrix} \quad \text{and} \quad \tilde{s}_{\lambda_i} := \begin{pmatrix} s_{1\lambda_{i\sigma}} \\ s_{1\lambda_{i\rho}} \\ \vdots \\ s_{m_{\lambda_{i\rho}}^m} \\ s_{m_{\lambda_{i\sigma}}^m} \end{pmatrix}, \quad (18)
\]

with \(s_{\alpha_i} := (f_{1i}^* - f_{m_0,i}^*, \ldots, f_{m_0-1,i}^* - f_{m_0,i}^*) / f_{m_0}(Y_i|X_i; Z_i; \theta_{m_0}^*), s_{\gamma_i} := Z_i \sum_{j=1}^{m_0} w_{j,i}^* H_j^{*1}, \)

and

\[
s_{(\theta, \sigma)i} := \begin{pmatrix} w_{1,i}^* H_{1,1,i}^{*1} \\ \vdots \\ w_{m_0,i}^* H_{m_0,1,i}^{*1} \\ w_{1,i}^* H_{1,1,i}^{*2} \\ \vdots \\ w_{m_0,i}^* H_{m_0,1,i}^{*2} \\ \vdots \\ w_{1,i}^* H_{1,1,i}^{*2} \\ \vdots \\ w_{m_0,i}^* H_{m_0,1,i}^{*2} \end{pmatrix}, \quad s_{\lambda_{i\alpha}}^h := \begin{pmatrix} w_{h,i}^* H_{h,i}^{3*} \\ w_{h,i}^* H_{h,i}^{4*} \\ w_{h,i}^* H_{h,i}^{2*} X_i \\ w_{h,i}^* H_{h,i}^{3*} X_i \end{pmatrix}, \quad (19)
\]

where \(f_{j,i}^* := f(Y_i|X_i; Z_i; \gamma^*, \theta^*, \sigma_j^2), H_{j,i}^{*k} := H^k((Y_i - \mu_j^* - X_i^\top \beta_j^* - Z_i^\top \gamma^*)/\sigma_j^*),\) and \(w_{j,i}^* := \alpha_j^* f_{j,i}^*/f_{m_0}(Y_i|X_i; Z_i; \theta_{m_0}^*).\) Define \(\tilde{\mathcal{L}} := E[\tilde{s}_i\tilde{s}_i^\top], \tilde{\mathcal{L}}_{\eta} := E[\tilde{s}_{\eta_i}\tilde{s}_{\eta_i}^\top], \tilde{\mathcal{L}}_{\lambda\eta} := E[\tilde{s}_{\lambda_i}\tilde{s}_{\lambda_i}^\top]\).
$E[\mathbf{s}_\lambda \mathbf{s}_\eta^\top], \tilde{\mathbf{I}}_{\eta \lambda} := \tilde{\mathbf{I}}_{\lambda \eta}, \tilde{\mathbf{I}}_\lambda := E[\mathbf{s}_\lambda \mathbf{s}_\lambda^\top], \text{ and } \tilde{\mathbf{I}}_{\lambda \eta} := \tilde{\mathbf{I}}_\lambda - \tilde{\mathbf{I}}_{\lambda \eta} \tilde{\mathbf{I}}_{\eta \lambda}^{-1} \tilde{\mathbf{I}}_{\eta \lambda}$. Let $\mathbf{S}_{\lambda \eta} := ((\mathbf{S}^h_{\lambda \eta})^\top, \cdots, (\mathbf{S}^{m_0}_{\lambda \eta})^\top)^\top \sim N(0, \tilde{\mathbf{I}}_{\lambda \eta})$ be an $\mathbb{R}^{m_0 \times m}$-valued random vector, and define $\mathbf{I}^h_{\lambda \eta} := E[\mathbf{S}^h_{\lambda \eta} (\mathbf{S}^h_{\lambda \eta})^\top]$ and $\mathbf{W}_{\lambda \eta} := (\mathbf{I}^h_{\lambda \eta})^{-1} \mathbf{S}^h_{\lambda \eta}$. Similar to $\hat{\mathbf{I}}^j_\lambda$ in the test of homogeneity, define $\hat{t}^j_{\lambda,h}$ by $r^j_{\lambda,h}(\hat{t}^j_{\lambda,h}) = \inf_{t_{\lambda} \in \mathbf{I}^j_{\lambda,h}} r^j_{\lambda,h}(t_{\lambda})$ for $j = 1, 2$, where $r^j_{\lambda,h}(t_{\lambda}) := (t_{\lambda} - \mathbf{W}_{\lambda,h})^\top \mathbf{I}^h_{\lambda \eta} (t_{\lambda} - \mathbf{W}_{\lambda,h})$. The following proposition gives the asymptotic null distribution of the LRT statistic for testing $H_{01}$. In the neighborhood of $\Upsilon^*_h$, the log-likelihood function permits a similar quadratic approximation to the one we derived in Section 3. Consequently, the LRT statistic is asymptotically distributed as the maximum of $m_0$ random variables, each of which is the maximum of two random variables.

**Assumption 4.** (a) $\alpha^*_j \in [\epsilon_1, 1 - \epsilon_1]$ for $j = 1, \ldots, m_0$. (b) $\min_{(j,k) \in \{1, \ldots, m_0\}} \{\sigma^*_j/\sigma^*_k\} > \epsilon$. (c) $\tilde{\mathbf{I}}$ is finite and nonsingular.

**Proposition 5.** Suppose that Assumptions 1 and 4 hold. Then, under the null hypothesis $H_0 : m = m_0, LR_{n, m_0}^{m_0} (\epsilon_1) \rightarrow_d \max \{v_1, \ldots, v_{m_0}\}$, where $v_h := \max \{(\hat{t}^1_{\lambda,h})^\top \mathbf{I}^h_{\lambda \eta} \hat{t}^1_{\lambda,h}, (\hat{t}^2_{\lambda,h})^\top \mathbf{I}^h_{\lambda \eta} \hat{t}^2_{\lambda,h}\}$.

In the remainder of this section, we derive a necessary and sufficient condition under which the LRT statistic for testing $H_{02}$ has finite Fisher information. For brevity, we focus on the case without $(\mathbf{X}, \mathbf{Z})$. The score for testing $H_{0,2h} : \alpha_h = 0$ takes the form $\nabla_{\alpha_h} \ln f_{m_0+1}(Y_i; \boldsymbol{\theta}_{m_0+1}) = [f(Y_i; \mu_h, \sigma^2_h) - f(Y_i; \mu^*_h, \sigma^2^*_h)]/f_{m_0}(Y_i; \boldsymbol{\theta}_{m_0})$. Define the subset of $\Upsilon^*$ corresponding to $H_{0,2h} : \alpha_h = 0$ as $\Upsilon^*_{2h} := \{\boldsymbol{\theta}_{m_0+1} \in \Theta_{\sigma_{m_0+1}} : \alpha_h = 0; \alpha_j = \alpha^*_j \text{ and } (\mu_j, \sigma^2_j) = (\mu^*_j, \sigma^2^*_j) \text{ for } j < h; \alpha_j = \alpha^*_j-1 \text{ and } (\mu_j, \sigma^2_j) = (\mu^*_j, \sigma^2^*_j) \text{ for } j > h + 1\}$. Because $(\mu_h, \sigma^2_h)$ is not identified when $\alpha_h = 0$, the Fisher information of the LRT for testing $H_{0,2h} : \alpha_h = 0$ depends on the supremum of the variance of $\nabla_{\alpha_h} \ln f_{m_0+1}(Y_i; \boldsymbol{\theta}_{m_0+1})$ over $\boldsymbol{\theta}_{m_0+1} \in \Upsilon^*_{2h}$. As shown in the following proposition, the Fisher information is infinite, unless a stringent restriction is imposed on the admissible values of $\sigma^2_j$.

**Proposition 6.** $\sup_{\boldsymbol{\theta}_{m_0+1} \in \Upsilon^*_{2h}} E[\{\nabla_{\alpha_h} \ln (f_{m_0+1}(Y_i; \boldsymbol{\theta}_{m_0+1}))\}^2] < \infty$ if and only if $\max \{\sigma^2 : \sigma^2 \in \Theta_{\sigma}\} < 2 \max \{\sigma^2_1^*, \ldots, \sigma^2_{m_0}^*\}$. 

15
5 Modified EM test

In this section, we develop a test of \( H_0 : m = m_0 \) against \( H_1 : m = m_0 + 1 \) for model (16).

First, we develop a modified EM test statistic for testing \( H \). We construct \( m_0 \) intervals \( \{D_1^*, \ldots, D_{m_0}^*\} \) of admisible values of \((\theta, \sigma^2)\), such that \((\theta^*_h, \sigma^2_h) \in D_h^* \) but \((\theta^*_j, \sigma^2_j) \notin D_h^* \) for any \( j \neq h \). For example, as in our simulation, we may assume that \( \mu^*_h \)'s are distinct and set \( D_h^* = [\Omega_h, (\mu_1^* + \mu_2^*)/2] \times \Theta_\beta \times \Theta_\sigma \), \( D_j^* = [(\mu_j^* - 1 + \mu_j^*)/2, (\mu_j^* + \mu_j^* + 1)/2] \times \Theta_\beta \times \Theta_\sigma \) for \( j = 2, \ldots, m_0 - 1 \), and \( D_{m_0}^* = [(\mu_{m_0-1}^* + \mu_{m_0}^*)/2, \tilde{\theta}_\mu] \times \Theta_\beta \times \Theta_\sigma \), where \( \tilde{\theta}_\mu \) and \( \Omega_h \) are defined by \( \hat{\Theta}_\mu = [\hat{\Theta}_\mu; \hat{\Theta}_\mu] \) and may take either the value \(-\infty \) or \( \infty \).

Collect the mixing parameters of the \((m_0 + 1)\)-component model into one vector as \( \varsigma := (\theta_1^T, \ldots, \theta_{m_0+1}^T, \sigma_1^2, \ldots, \sigma_{m_0+1}^2)^T \in \Omega_\varsigma := \Theta_\theta^m \times \Theta_\sigma^m \). For \( h = 1, \ldots, m_0 \), define a restricted parameter space of \( \varsigma \) by \( \Omega_h^* := \{\varsigma \in \Omega_\varsigma : (\theta_j, \sigma_j^2) \in D_j^* \text{ for } j = 1, \ldots, h - 1; (\theta_h, \sigma_h^2), (\theta_{h+1}, \sigma_{h+1}^2) \in D_h^*; (\theta_j, \sigma_j^2) \in D_{j-1}^* \text{ for } j = h + 2, \ldots, m_0 + 1\} \). Let \( \hat{\Omega}_h \) and \( \hat{D}_h \) be consistent estimates of \( \Omega_h^* \) and \( D_h^* \), which can be constructed from a consistent estimate of the \( m_0 \)-component model. We test \( H_{0,1h} : (\theta_h, \sigma_h^2) = (\theta_{h+1}, \sigma_{h+1}^2) \) by estimating the \((m_0 + 1)\)-component model (17) under the restriction \( \varsigma \in \hat{\Omega}_h \). For example, when we test \( H_{0,11} : (\theta_1, \sigma_1^2) = (\theta_2, \sigma_2^2) \) in a three-component model, the restriction can be given as \((\theta_1, \sigma_1^2), (\theta_2, \sigma_2^2) \in \hat{D}_1 \) and \((\theta_3, \sigma_3^2) \in \hat{D}_2 \).

Define the penalized log-likelihood function for the \((m_0+1)\)-component model by \( PL_n(\vartheta_{m_0+1}) := L_n(\vartheta_{m_0+1}) + \sum_{j=1}^{m_0+1} p_n(\sigma_j^2) \), where \( p_n(\sigma^2) \) is a penalty function that satisfies Assumptions 5 and 6 below. Let \( \mathcal{T} \) be a finite set of numbers from \((0,0.5] \). For each \( \tau_0 \in \mathcal{T} \), define the restricted penalized MLE as \( \hat{\vartheta}_{m_0+1}^{(1)}(\tau_0) := \arg\max_{\vartheta_{m_0+1} \in \Theta^h(\tau_0)} PL_n(\vartheta_{m_0+1}) \), where \( \Theta^h(\tau_0) := \{\vartheta_{m_0+1} \in \Theta_{m_0+1} : \alpha_h/(\alpha_h + \alpha_{h+1}) = \tau_0 \text{ and } \varsigma \in \hat{\Omega}_h \} \).

Starting from \( \hat{\vartheta}_{m_0+1}^{(1)}(\tau_0) \), we update \( \vartheta_{m_0+1} \) by the following generalized EM algorithm. Henceforth, we suppress \( (\tau_0) \) from \( \hat{\vartheta}_{m_0+1}^{(k)}(\tau_0) \). Suppose we have already calculated \( \hat{\vartheta}_{m_0+1}^{(k)} \).

For \( i = 1, \ldots, n \) and \( j = 1, \ldots, m_0 + 1 \), define the weights for an E-step as \( w_{ij}^{(k)} := \alpha_j^{(k)} f(Y_i|X_i, Z_i; \gamma^{(k)}, \theta_j^{(k)}, \sigma_j^{2(k)})/f_{m_0+1}(Y_i|X_i, Z_i; \vartheta_{m_0+1}^{(k)}) \).
In an M-step, update \( \mathbf{\theta}_{m_0+1} \) by \( \gamma^{(k+1)} := \left( \sum_{i=1}^{n} \mathbf{z}_i \mathbf{z}_i^\top \right)^{-1} \left[ \sum_{i=1}^{n} \mathbf{z}_i (Y_i - \sum_{j=1}^{m_0+1} w^{(k)}_{ij} \bar{X}_i \mathbf{\theta}_j^{(k)}) \right] \),

and for \( j = 1, \ldots, m_0 + 1 \), by \( \alpha_j^{(k+1)} := n^{-1} \sum_{i=1}^{n} w^{(k)}_{ij} \) and

\[
\mathbf{\theta}_j^{(k+1)} := \left( \sum_{i=1}^{n} w^{(k)}_{ij} \bar{X}_i \bar{X}_i^\top \right)^{-1} \left[ \sum_{i=1}^{n} w^{(k)}_{ij} \bar{X}_i (Y_i - Z_i^\top \gamma^{(k+1)}) \right],
\]

\[
\sigma_j^{2(k+1)} := \arg \max_{\sigma_j^2} \left\{ \sum_{i=1}^{n} w^{(k)}_{ij} \ln f(Y_i|X_i, Z_i; \gamma^{(k+1)}, \mathbf{\theta}_j^{(k+1)}, \sigma_j^2) + p_n(\sigma_j^2) \right\},
\]

where \( \bar{X}_i := (1, \mathbf{X}_i^\top)^\top \). The penalized likelihood value never decreases after each generalized EM step (Dempster et al., 1977, Theorem 1). Note that \( \mathbf{\theta}_m^{(k)} \) for \( k \geq 2 \) does not use the restriction \( \hat{\Omega}_h \). For each \( \tau_0 \in T \) and \( k \), define

\[
M_n^{h(k)}(\tau_0) := 2 \left\{ L_n(\mathbf{\theta}_m^{(k)}(\tau_0)) - L_{0,n}(\tilde{\mathbf{\theta}}_{m_0}) \right\},
\]

where \( \tilde{\mathbf{\theta}}_{m_0} := \arg \max_{\mathbf{\theta}_{m_0} \in \Theta_{m_0}} L_{0,n}(\mathbf{\theta}_{m_0}) + \sum_{j=1}^{m} p_n(\sigma_j^2) \).

Finally, with a pre-specified number \( K \), define the local modified EM test statistic for testing \( H_{0,1} \) by taking the maximum of \( M_n^{h(k)}(\tau_0) \) over \( \tau_0 \in T \) as \( \text{EM}_n^{h(K)} := \max \left\{ M_n^{h(K)}(\tau_0) : \tau_0 \in T \right\} \). The modified EM test statistic is defined as the maximum of \( m_0 \) local modified EM test statistics: \( \text{EM}_n^{(K)} := \max \left\{ \text{EM}_n^{1(K)}, \text{EM}_n^{2(K)}, \ldots, \text{EM}_n^{m_0(K)} \right\} \). The following proposition shows that for any finite \( K \), the modified EM test statistic is asymptotically equivalent to the LRT statistic for testing \( H_{01} \). Assumptions 5 and 6 are adopted from Chen et al. (2008) and Chen and Li (2009).

**Assumption 5.** (a) \( \sup_{\sigma^2 > 0} \max \{0, p_n(\sigma^2)\} = o(n) \) and \( p_n(\sigma^2) = o(n) \) at any fixed \( \sigma > 0 \). (b) For any \( \sigma \in (0, 8/(nM)] \), we have \( p_n(\sigma^2) \leq 5(\ln n)^2 \ln \sigma \) for a sufficiently large \( n \), where \( M = \sup_{y,z,x} f_{m_0}(y|x, z; \mathbf{\theta}_{m_0}^*) \).

**Assumption 6.** \( \nabla_{\sigma^2} p_n(\sigma^2) = o_p(n^{1/4}) \).

**Proposition 7.** Suppose that Assumptions 1, 4, 5, and 6 hold. Then, under the null hypothesis \( H_0 : m = m_0 \), for any fixed finite \( K \), as \( n \to \infty \), \( \text{EM}_n^{(K)} \to_d \max \{v_1, \ldots, v_{m_0}\} \), where
the $v_h$'s are given in Proposition 5.

6 Asymptotic testing power

In this section, we study the asymptotic testing power of the modified EM test for testing $H_0 : m = 1$ against $H_A : m = 2$. Consider the following local alternative to the homogeneous model $f(y|x, z; \gamma^*, \theta^*, \sigma^{2*})$. For $\alpha^* \in (0, 1)$ and $\Delta \in \mathbb{R}^q$, let $H_{(\alpha^*, \Delta)}^n : \alpha = \alpha^*, \gamma = \gamma^*, (\nu_\theta, \nu_\sigma) = (\theta^*, \sigma^{*2})$, and $t_{\lambda n} = \Delta$. This local alternative is contiguous to the null distribution $f(y|x, z; \gamma^*, \theta^*, \sigma^{2*})$. Using our quadratic-form approximation, the asymptotic distribution of the modified EM statistic under $H_{(\alpha^*, \Delta)}^n$ is derived from LeCam’s contiguity theory. The following proposition shows that the modified EM test for testing $H_0 : m = 1$ is locally optimal for this class of alternatives.

**Proposition 8.** Suppose that Assumptions 1 and 2 and $H_{(\alpha^*, \Delta)}^n$ hold with $\alpha^* \in [\epsilon_1, 1-\epsilon_1]$. Let $W_\lambda \sim N(0, I^{-1}_\lambda \gamma)$ and let $\hat{t}_{\lambda n}$ be an estimator of $t_{\lambda n}$ in (11). Define $\hat{t}^1_{\lambda, \Delta}$ in the same manner as $\hat{t}^1_{\lambda}$ in (15) but using $W_\lambda + \Delta$ in place of $W_\lambda$. Then, (a) $LR_{1,n}(\epsilon_1), EM^{(K)}_n \rightarrow_d (W_\lambda + \Delta)^\top \mathcal{I}_{\lambda, \eta}(W_\lambda + \Delta)$ if the model has no conditioning variable $X$, (b) $LR_{1,n}(\epsilon_1), EM^{(K)}_n \rightarrow_d \max\{\hat{t}^1_{\lambda, \Delta} \mathcal{I}_{\lambda, \eta} \hat{t}^1_{\lambda, \Delta}, (\hat{t}^2_{\lambda, \Delta}) \mathcal{I}_{\lambda, \eta} \hat{t}^2_{\lambda, \Delta}\}$, and (c) $\hat{t}_{\lambda n} \rightarrow_d \hat{t}^1_{\lambda, \Delta} \hat{\xi} + \hat{t}^2_{\lambda, \Delta} (1 - \hat{\xi})$, where $\hat{\xi} = 1\{\hat{t}^1_{\lambda, \Delta} \mathcal{I}_{\lambda, \eta} \hat{t}^1_{\lambda, \Delta} > (\hat{t}^2_{\lambda, \Delta}) \mathcal{I}_{\lambda, \eta} \hat{t}^2_{\lambda, \Delta}\}$.

As highlighted by the use of constant $\epsilon_1$ in the definition of $LR_{1,n}(\epsilon_1)$, Proposition 8 does not cover a sequence of local alternatives where $\alpha$ approaches 0.

7 Simulation

7.1 Choice of penalty function

To apply our modified EM test, we need to specify the set $\mathcal{T}$, number of iterations $K$, and penalty function for $p_n(\sigma^2)$. Based on our experience, we recommend $\mathcal{T} = \{0.5\}$ and $K = 2$
or 3; following the recommendation given by Chen et al. (2012), we set

\[ p_n(\sigma_j^2; \hat{\sigma}_j^2) = -a_n \left\{ \frac{\hat{\sigma}_j^2}{\sigma_j^2} + \ln\left( \frac{\sigma_j^2}{\hat{\sigma}_j^2} \right) - 1 \right\} , \]  

(22)

where \( \hat{\sigma}_j^2 \) is the estimate from the \( m_0 \)-component model. \( p_n(\sigma_j^2; \hat{\sigma}_j^2) \) satisfies Assumptions 5 and 6 if \( a_n = o_p(n^{1/4}) \). In models with a regressor, we use an additional restriction \( \sigma_j \geq 0.01\hat{\sigma}_j \), which does not change the theoretical results but improves finite sample performance.

For the model without a conditioning variable \( \mathbf{X} \), we set \( a_n = 0.25 \) for testing \( H_0 : m = 1 \) while we develop the following data-dependent empirical formula for tuning parameter \( a_n \) for the cases where \( m_0 = 2 \) and \( m_0 = 3 \):

\[
a_n = \begin{cases} 
1.8q_n(\omega_{12}, n)/(1 + q_n(\omega_{12}, n)) & \text{for } m_0 = 2, \\
1.5q_n(\omega_{12}, \omega_{23}, n)/(1 + q_n(\omega_{12}, \omega_{23}, n)) & \text{for } m_0 = 3,
\end{cases}
\]

(23)

with \( q_n(\omega_{12}, n) = \exp(-1.645 - 0.435 \ln(\omega_{12}/(1 - \omega_{12})) - 101.60/n) \) and \( q_n(\omega_{12}, \omega_{23}, n) = \exp(-1.679 - 0.232 \ln(\omega_{12}\omega_{23}/[(1 - \omega_{12})(1 - \omega_{23})]) - 175.67/n) \), where \( \omega_{12} \) and \( \omega_{23} \) are misclassification rates (Maitra and Melnykov, 2010). In a two-component normal mixture model, \( \omega_{1|2} = \Pr(\alpha_1 f(Y; \mu_1, \sigma_1^2) > \alpha_2 f(Y; \mu_2, \sigma_2^2)) \) gives the probability that an observation \( Y \) from component 2 is misclassified into component 1. Similarly, let \( \omega_{2|1} \) denote the opposite misclassification rate. Then, \( \omega_{12} \) is defined as the average of \( \omega_{1|2} \) and \( \omega_{2|1} \), and \( \omega_{23} \) is defined as the average of \( \omega_{2|3} \) and \( \omega_{3|2} \). The empirical formula in (23) is obtained through computer experiments that are similar to those in Chen and Li (2009) and Chen et al. (2012).

For the model with a conditioning variable \( \mathbf{X} \), the value of \( a_n \) that gives accurate Type I errors is sensitive to the dimension of \( \mathbf{X} \). For testing \( H_0 : m = 1 \), we choose the value of \( a_n \) depending on the dimension of \( \mathbf{X} \) so that Type I errors are accurate at \( n = 200 \) using 10,000 replications as described in the last column of Table 4. For the cases where \( m_0 = 2 \) and \( m_0 = 3 \), developing a data-dependent empirical formula for \( a_n \) is difficult, and therefore, we set the value of \( a_n \) as in Table 4 and use both asymptotic and bootstrap critical values.
7.2 Simulation results

For the model without conditioning variable $X$, we examine the finite sample performance of our proposed modified EM test by simulations and compare it with that of the EM test of Chen et al. (2012) [CLF, hereafter]. Computation was done using R (R Core Team, 2014). We use 5,000 replications, and the sample sizes are set to 200 and 400. The $m_0$-component estimate $\tilde{\vartheta}_{m_0}$ in (21) is computed with the penalty function $p_n(\sigma_j^2)$ defined in (22), where $a_n = 1/n$ and $\hat{\sigma}_j^2$ is set to the sample variance of the data for all $j$.

We simulated Type I error rates for 12 null models with orders 2 and 3 that are the same as in CLF, as specified in Table 1. The simulation results for $H_0: m = 2$ are summarized in Figure 1. Overall, the finite sample size properties of the modified EM test are very good and similar to those of the EM test of CLF, even though the size of the modified EM test tends to have more dispersion across models. Figure 2 reports the simulation results for $H_0: m = 3$. The results are similar to those for $H_0: m = 2$. We examined the power of the modified EM test by considering 10 alternative models with order 3, and 8 alternative models with order 4. The simulation results are summarized in Tables 2 and 3. In both tables, the first four models are the same as those used in CLF. In many cases, our modified EM test has stronger power than the EM test of CLF. The power difference is the most significant when $\sigma_j$s are heterogeneous.

We also examine the performance of our proposed modified EM test for the model with conditioning variable $X$. Computation was done using Matlab. We use 10,000 replications when testing $H_0: m = 1$, and 1,000 and 500 replications when testing $H_0: m = 2$ and $H_0: m = 3$, respectively. For testing $H_0: m = 1$, Table 4 reports that our choice of $a_n$ gives accurate Type I errors even at $n = 100$ for $\text{dim}(X) = 1, \ldots, 4$. Table 6 reports the power simulation results under 8 alternative models as specified in Table 5. The power tends to decline with the dimension of $X$ but increases with the sample size.

We simulated Type I error rates for 16 null models as specified in Table 7 with orders 2 and
3 and with a scalar conditioning variable. Figures 3 and 4 summarize the simulation results, where bootstrap critical values with 199 bootstrap replications and asymptotic critical values are used. When compared with Figures 1 and 2, the Type I error rates vary more across the models. When testing $H_0: m = 2$, the bootstrap test performs well, while the asymptotic test is oversized in some models when $n = 200$. When testing $H_0: m = 3$, the modified EM test performs fairly well, even though it tends to overreject and underreject when $n = 200$ and $n = 400$, respectively. Tables 8 and 9 report power simulation results when testing $H_0: m = 2$ and $H_0: m = 3$, respectively. The modified EM test has a good power under both bootstrap and asymptotic critical values.

8 Empirical Applications

8.1 Analysis of Stock Returns

Using 4,639 observations of daily returns for 30 stocks in the Dow Jones Industrial Average, Kon (1984) estimated a finite mixture of normal distributions. Kon (1984) selected the number of components using LRT, but based on the invalid chi-squared asymptotic distribution. We re-estimated the number of components by sequentially applying the modified EM test with $K = 2$ to test $m = k$ against the alternative $m = k + 1$ for $k = 1, 2, 3$ at the $(1/3) \times 5\%$ significance level. Table 10 shows the frequency of the number of components selected by Kon (1984), the modified EM test, Akaike Information Criteria (AIC), and Bayesian Information Criteria (BIC). In Kon’s dataset, some stocks return data contain a substantial number of observations with $y_i = 0.0$, which leads to degeneracy (i.e, $\hat{\mu}_j = 0$ and $\hat{\sigma}_j \to 0$). To deal with this problem, we discarded estimates such that $\max_j(\hat{\sigma}_j)/\min_j(\hat{\sigma}_j) > 100$. Kon (1984) often chooses a two-component model over other procedures. Compared with the modified EM test, AIC tends to select a larger number of components, whereas BIC selects a model with fewer components.
8.2 Analysis of Differential Gene Expression

A finite normal mixture model provides an approach to finding differentially expressed genes by means of the posterior probability that an individual gene is non-differentially expressed (Lee et al., 2000; Efron et al., 2001). We analyzed the leukemia dataset of Golub et al. (1999), which consists of the quantitative expression levels of 7,129 genes from 47 patients with acute lymphoblastic leukemia (ALL) and 25 patients with acute myeloid leukemia (AML). The data can be downloaded from [http://waldo.wi.mit.edu/MPR/data_set_ALL_AML.html](http://waldo.wi.mit.edu/MPR/data_set_ALL_AML.html). Using the approach of Efron (2004), we computed the two-sample $t$-statistic comparing 47 ALL patients with 25 AML patients for each of the 7,129 genes, and obtained $z$-values as $z = \Phi^{-1}(1 - p)$, in which $p$ is the $p$-value of the $t$-statistic and $\Phi$ is the $N(0, 1)$ distribution function. If the gene is not differentially expressed, the corresponding $z$-value should then follow $N(0, 1)$. A large $z$-value implies an overexpressed gene in patients with ALL. We applied normal mixtures to model the $z$-values. Table 11 reports the parameter estimates $\hat{\vartheta}_m$, the $p$-value of the modified EM test using $K = 2$ in testing $H_0 : m = m_0$ against $H_0 : m = m_0 + 1$, AIC, and BIC for $m_0 = 1, 2, 3$. The modified EM test and AIC selected $m = 3$, whereas BIC chose $m = 2$. As shown in Figure 5, the three-component model more clearly captured data density, as compared to the two-component model. The three-component model classified approximately 26.8% of the genes as overexpressed in patients with ALL, whereas the two-component model estimated that $\alpha_2$ comprised approximately 35.6% of the genes, and classified more genes as overexpressed compared to the three-component model.

8.3 Cross-Country Growth Regression

Mankiw et al. (1992) estimate a cross-country growth regression model to investigate a hypothesis that a country’s growth rate is negatively related to its initial per capita gross domestic product (GDP). We examined the possibility of multiple regimes by considering the following mixture of regressions: $\ln(Y/L)_{i,1985} - \ln(Y/L)_{i,1960} = \mu_j + \beta_{1j} \ln(Y/L)_{i,1960} + \ldots$
\[ \beta_{2j} \ln(I/Y)_i + \beta_{3j} \ln(n_i + 0.05) + \epsilon_{ji}, \text{ where } \epsilon_{ji} \sim iid \ N(0, \sigma_j^2), \] (\(Y/L\)) represents country i’s per capita GDP at year t, (I/Y)_i is the average ratio of investment to GDP from 1960 to 1985, and n_i is the average growth rate of working-age population from 1960 to 1985. We used the data of 75 “Intermediate” countries from Mankiw et al. (1992) that exclude small countries and countries with poor measurement of GDP. When testing \(H_0 : m = 1\) against \(H_0 : m = 2\), the asymptotic p-values of the modified EM test are 0.064 and 0.057 at \(K = 2\) and 3, respectively, providing some evidence for two regimes. On the other hand, the bootstrapped p-values of the modified EM test for testing \(H_0 : m = 2\) against \(H_0 : m = 3\) are 0.311 and 0.315 at \(K = 2\) and 3, respectively, providing no evidence for three regimes.

8.4 Spread of a Viral Infection in Potato Plants

Turner (2000) uses normal regression mixtures to model the spread of a viral infection in potato plants by aphids. The data set is from an experiment described in Boiteau et al. (1998). In each experiment, a grid of 81 potato plants was placed on the floor of a flight chamber, and varying number of aphids between 1 and 320 were released near the center of the grid, and the plants were taken out to measure the number of infected plants after one day. A total of 51 such experiments were conducted. The response variable is the number of infected plants, and the explanatory variables are the constant and the number of aphids. When testing \(H_0 : m = 1\) against \(H_A : m = 2\), the asymptotic p-values of the modified EM test are 0.000 at \(K = 2\) and 3, providing strong evidence against the one-component model. On the other hand, when testing \(H_0 : m = 2\) against \(H_A : m = 3\), the bootstrapped p-values of the modified EM test are 0.142 and 0.154 at \(K = 2\) and 3, respectively. Therefore, a two-component model is not rejected at the 10% significance level.
9 Supplemental Materials

Technical Details: The supplementary appendix contains proofs, auxiliary results, details of computer experiments, and additional results from empirical examples.
