- In the linear regression model,

$$y_i = \beta_0 + \beta_1 x_i + \epsilon_i$$

the most important assumption for $\hat{\beta}_1^{\text{OLS}}$ to be consistent is exogeneity,

$$E[x_i \epsilon_i] = 0$$

- Exogeneity is often an implausible assumption
- If we have an additional variable z_i with certain properties than we can still consistently estimate β_1 even when $E[x_i \epsilon_i] \neq 0$
- New notation: $\hat{\beta}^{\text{OLS}}$ instead of just $\hat{\beta}$ for OLS estimates

- Education (s_i) and log wages ($\log w_i$)

$$\log w_i = \beta_0 + \beta_1 s_i + \epsilon_i$$

- Suppose we want the causal effect of education on wages – then we want to hold constant everything else that affects wages
- We can never hold everything else constant, but we know that

$$\text{plim } \hat{\beta}_1^{\text{OLS}} = \beta_1 + \frac{\text{Cov}(s_i, \epsilon_i)}{\text{Var}(s_i)}$$

so as long as whatever we are not holding constant (i.e. ϵ_i) is uncorrelated with s_i we are okay

- But it is very likely that there is unobserved ability, a_i , (IQ, work ethic, etc) that affects both education and wages

$$\log w_i = \beta_0 + \beta_1 s_i + \underbrace{\beta_2 a_i + u_i}_{=\epsilon_i}$$

- Then,

$$\text{plim } \hat{\beta}_1^{\text{OLS}} = \beta_1 + \beta_2 \frac{\text{Cov}(s_i, a_i)}{\text{Var}(s_i)} + \frac{\text{Cov}(s_i, u_i)}{\text{Var}(s_i)}$$

$$\log w_i = \beta_0 + \beta_1 s_i + \epsilon_i$$

- Suppose we observe a variable z_i such that $E[z_i \epsilon_i] = 0$, then

$$\begin{aligned} 0 &= E[z_i \epsilon] \\ &= E[z_i (\log w_i - \beta_0 - \beta_1 s_i)] \end{aligned} \tag{1}$$

we also know $E[\epsilon_i] = 0$, so

$$0 = E[(\log w_i - \beta_0 - \beta_1 s_i)] \tag{2}$$

IV estimates of return to education

replace the $E[\cdot]$ with $\frac{1}{n} \sum_{i=1}^n$ and we have two equations to estimate two parameters β_0, β_1

$$0 = \frac{1}{n} \sum_{i=1}^n z_i \left(\log w_i - \hat{\beta}_0^{IV} - \hat{\beta}_1^{IV} s_i \right) \quad (3)$$

$$0 = \frac{1}{n} \sum_{i=1}^n \left(\log w_i - \hat{\beta}_0^{IV} - \hat{\beta}_1^{IV} s_i \right) \quad (4)$$

- Note similarity to OLS first order conditions
- This approach to estimation – start with an assumption about some expectations (moments) being zero and use them to derive an equation to use for estimation – is called the (generalized) method of moments
- (1) and (2) are called the (population) moment conditions

yes, as long as $\text{Cov}(z, s) \neq 0$ (and $\text{Cov}(z, \epsilon) = 0$, which we already assumed)

- How can we find such a z ?

Card (1993) instrument: nearby college

- $nearc4_i = 1$ if i grew up in a county with a four-year college, else 0
- Two requirements to be a valid instrument:
 - ① (exogenous) $E[nearc4_i \epsilon_i] = 0$
 - ② (relevant) $Cov(nearc4_i, s_i) \neq 0$
- Relevance can be checked empirically
 - $\widehat{Cov}(nearc4_i, s_i) = 0.18$
 - Regress s_i on $nearc4_i$

	Model 1

Card (1993) instrument: nearby college

- Exogeneity cannot be tested empirically
 - Card (1993) discusses why maybe not $E[\text{nearby college}_i \epsilon_i] = 0$
 - Families that value education might live near colleges
 - High schools and elementary schools might be higher quality near colleges
 - It's a challenge to show these concerns are not a problem (we will discuss it more later)

- Model

$$y_i = \beta_0 + \beta_1 x_i + \epsilon_i \quad (5)$$

- Assumptions:

IV.1 Linearity: (5) holds

IV.2 Independent observations

IV.3 Relevance (rank condition): $\text{Cov}(z, x) \neq 0$

IV.4 Exogeneity: $E[z_i \epsilon_i] = 0$

Note: these are the same as for OLS except the rank condition and exogeneity assumptions are now about the instrument, z , instead of the regressor, x

- Relevance + exogeneity = z affects y only through x
- Terminology:
 - z_i is an **instrument** or **instrumental variable**
 - (5) is the **structural equation**
 - x_i is an **endogenous regressor**
 - The regression of x on z is the **first stage**

Example:
return to
education

Lemieux and Card
(2001)

Fang et al. (2012)

References

- Consider $E[\hat{\beta}_1^{IV}]$

$$\begin{aligned} E[\hat{\beta}_1^{IV}] &= E \left[\frac{\sum_{i=1}^n (z_i - \bar{z}) y_i}{\sum_{i=1}^n (z_i - \bar{z}) x_i} \right] \\ &= E \left[\frac{\sum_{i=1}^n (z_i - \bar{z}) (\beta_0 + \beta_1 x_i + \epsilon_i)}{\sum_{i=1}^n (z_i - \bar{z}) x_i} \right] \\ &= \beta_1 + E \left[\frac{\sum_{i=1}^n (z_i - \bar{z}) \epsilon_i}{\sum_{i=1}^n (z_i - \bar{z}) x_i} \right] \\ &\neq \beta_1 \end{aligned}$$

- Cannot show $E \left[\frac{\sum_{i=1}^n (z_i - \bar{z}) \epsilon_i}{\sum_{i=1}^n (z_i - \bar{z}) x_i} \right] = 0$ because of x_i in denominator and

$$E \left[\frac{\sum_{i=1}^n (z_i - \bar{z}) \epsilon_i}{\sum_{i=1}^n (z_i - \bar{z}) x_i} \right] \neq \frac{E \left[\sum_{i=1}^n (z_i - \bar{z}) \epsilon_i \right]}{E \left[\sum_{i=1}^n (z_i - \bar{z}) x_i \right]}$$

IV is consistent

Introduction

Example: return to education

Statistical properties

Bias

Consistency

Asymptotic
distribution

IV when exogeneity
fails

IV for multiple regression

Example: return to education

Lemieux and Card
(2001)

Fang et al. (2012)

References

- As in the education example,

$$\begin{aligned}
 \text{plim } \hat{\beta}_1^{\text{IV}} &= \text{plim } \frac{\frac{1}{n} \sum_{i=1}^n (z_i - \bar{z}) y_i}{\frac{1}{n} \sum_{i=1}^n (z_i - \bar{z}) x_i} \\
 &= \beta_1 + \text{plim } \frac{\frac{1}{n} \sum_{i=1}^n (z_i - \bar{z}) \epsilon_i}{\frac{1}{n} \sum_{i=1}^n (z_i - \bar{z}) x_i} \\
 &= \beta_1 + \frac{\text{plim } \frac{1}{n} \sum_{i=1}^n z_i \epsilon_i - \text{plim } \bar{z} \text{plim } \bar{\epsilon}}{\text{plim } \frac{1}{n} \sum_{i=1}^n z_i x_i - \text{plim } \bar{z} \text{plim } \bar{x}} \\
 &= \beta_1 + \frac{E[z\epsilon]}{E[zx] - E[z]E[x]} = \beta_1 + \frac{\text{Cov}(z, \epsilon)}{\text{Cov}(z, x)} \\
 &= \beta_1
 \end{aligned}$$

- So IV is biased but consistent
- Another useful way of expressing $\hat{\beta}_1^{\text{IV}}$ is as the reduced form divided by the first stage:

IV is consistent

Introduction

Example:
return to
education

Statistical properties

Bias

Consistency

Asymptotic
distribution

IV when exogeneity
fails

IV for multiple regression

Example:
return to
education

Lemieux and Card
(2001)

Fang et al. (2012)

References

- Reduced form:

$$y_i = \pi_{y,0} + \pi_{y,1}Z_i + u_i$$

$$\text{OLS estimate} = \hat{\pi}_{y,1} = \frac{\widehat{\text{Cov}}(z,y)}{\widehat{\text{Var}}(z)}$$

- First stage:

$$x_i = \pi_{x,0} + \pi_{x,1}Z_i + v_i$$

$$\text{OLS estimate} = \hat{\pi}_{x,1} = \frac{\widehat{\text{Cov}}(x,z)}{\widehat{\text{Var}}(z)}$$

- Then,

$$\hat{\beta}^{\text{IV}} = \frac{\widehat{\text{Cov}}(z,y)}{\widehat{\text{Cov}}(z,x)} = \frac{\widehat{\text{Cov}}(z,y)/\widehat{\text{Var}}(z)}{\widehat{\text{Cov}}(z,x)/\widehat{\text{Var}}(z)} = \frac{\hat{\pi}_{y,1}}{\hat{\pi}_{x,1}}$$

- People sometimes defend an instrument by saying: “even though it might not be true that $E[z\epsilon] = 0$, it is likely that the correlation between z and ϵ is smaller than the correlation between x and ϵ . Therefore we prefer the IV estimate to the OLS estimate.”
Is this argument correct?

IV without exogeneity

- Express in terms of correlations:¹

$$\text{plim } \hat{\beta}_1^{\text{IV}} - \beta_1 = \frac{\rho_{z,\epsilon} \sqrt{\text{Var}(z)\text{Var}(\epsilon)}}{\rho_{z,x} \sqrt{\text{Var}(z)\text{Var}(x)}} = \frac{\rho_{z,\epsilon}}{\rho_{z,x}} \sqrt{\frac{\text{Var}(\epsilon)}{\text{Var}(x)}}$$

and

$$\text{plim } \hat{\beta}_1^{\text{OLS}} - \beta_1 = \frac{\rho_{x,\epsilon} \sqrt{\text{Var}(x)\text{Var}(\epsilon)}}{\text{Var}(x)} = \rho_{x,\epsilon} \sqrt{\frac{\text{Var}(\epsilon)}{\text{Var}(x)}}$$

- So IV is “less inconsistent” than OLS only if

$$\left| \frac{\rho_{z,\epsilon}}{\rho_{z,x}} \right| < |\rho_{x,\epsilon}|$$

- Just z being “less endogenous” or less correlated with ϵ is not enough
- No, the proposed argument is not correct

- Model

$$y_i = \beta_0 + \beta_1 x_{1,i} + \cdots + \beta_k x_{k,i} + \beta_{k+1} w_{1,i} + \cdots + \beta_{k+r} w_{r,i} + \epsilon_i \quad (6)$$

with instruments $z_{1,i}, \dots, z_{m,i}$

- Assumptions:

IV.1 Linearity: (6) holds

IV.2 Independent observations

IV.3 Relevance (rank condition): $m \geq k$ and (loosely speaking) each $x_{j,i}$ is correlated with some $z_{l,i}$

IV.4 Exogeneity: $E[w_{s,i} \epsilon_i] = 0$ for $s = 1, \dots, r$ and $E[z_{l,i} \epsilon_i] = 0$ for $l = 1, \dots, m$

- Terminology:

- $w_{s,i}$ are exogenous controls
- $x_{j,i}$ are endogenous regressors
- $z_{l,i}$ are instruments

Fang et al. (2012)

References

- $\hat{\beta}^{2SLS}$ is consistent and asymptotically normal
- Essential that x be regressed on both z and w in the first stage
- When calculating $\hat{\beta}^{2SLS}$ best not to perform two regressions
 - OLS standard errors of second stage regression are not correct for $\hat{\beta}^{2SLS}$
 - In R use `ivreg` or `fe1m`
- Test relevance condition: look at the F -statistic in for $H_0 : \pi_{x_j, z_1} = \dots = \pi_{x_j, z_m} = 0$ in the first stage
 - Rule of thumb: $F \geq 10$ is okay, $F < 10$ need to use another method (weak instruments)

Table: AK 1930-1939 IV estimates

Lemieux and Card (2001) “Education, earnings, and the ‘Canadian G.I. Bill’ ”

- Question: what is the causal effect of education on earnings?
- Strategy: use VRA as instrument for education
- Veteran Rehabilitation Act (1944)
 - Tuition + living expenses allowance of \$60 (\approx \$500 today) per month for university or vocational training
 - Different impact in Ontario and Quebec
 - Ontario had compulsory schooling until age 16, more universities, higher average education at start of WWII
 - Quebec had no compulsory schooling, few universities, lower average education at start of WWII; lower portion of veterans
 - VRA had smaller impact in Quebec than Ontario
- Instrument = Ontario \times university age in 1945
- Data: 1971 Census
 - Observations: 11,163 Ontario + 10,078 Quebec

* significant at the 10% level; ** significant at the 5% level; *** significant at the 1% level.

Table 5: Robustness check on instrument

Yearly earning in natural log as the dependent variable ^a	Two-year control and Two-year treatment cohorts		Two-year control cohort		Two-year treatment cohort	
	13 - 16 years old		15 - 16 years old		13 - 14 years old	
	Coeff.	S.E.	Coeff.	S.E.	Coeff.	S.E.
OLS						
School years completed	0.09	*** (0.01)	0.09	*** (0.01)	0.10	*** (0.02)
2SLS ^b						
School years completed	0.26	*** (0.09)	0.54	(1.11)	0.04	(0.22)

* significant at the 10% level; ** significant at the 5% level; *** significant at the 1% level.

^a All estimations have controlled for the other explanatory variables in Table 1.

^b Using the instrumental variables as those in Table 3 for various study cohorts respectively.

Table 6: Selected results by gender, urbanization, and province location (the “All” sample)

The dependent variable is the annual income in natural log	Coefficients on "School years completed"				
	OLS		2SLS		
	Coeff.	S.E.	Coeff.	S.E.	
By gender					
Female	0.09 ***	(0.01)	0.10 *	(0.05)	
Male	0.09 ***	(0.01)	0.51 **	(0.23)	
By urbanization					
Rural	0.09 ***	(0.01)	0.18 ***	(0.07)	
Urban	0.08 ***	(0.01)	0.14	(0.09)	
By province location					
Inland provinces	0.09 ***	(0.01)	0.12	(0.08)	
Coastal provinces	0.09 ***	(0.01)	0.37 ***	(0.12)	

* significant at the 10% level; ** significant at the 5% level; *** significant at the 1% level.
