Strategic
network
formation

References

- Network formation: model of which nodes are connected
- Goal: parsimonious, tractable, and estimable model that matches features of observed networks
- Types of models
 - Random network models: specify $P(i \& j \text{ connect} | \text{other connections, node characteristics})$
 - Strategic network formation: specify payoffs $u_i(G, \cdot)$ and equilibrium concept (e.g. pairwise stability)
 - G is pairwise stable if for each link neither player would be better off without it, and there are no two players would both be better off by adding a link
 - Payoffs could come from a subsequent game on the network

- Profits

$$\pi_i(q, G) = \eta_i q_i - \nu q_i^2 - b q_i \sum_{j \neq i} q_j + \rho \sum_{j=1}^n \sum_{j=1}^n a_{ij} q_i q_j - \zeta d_i$$

where

- A is collaboration network
- $\rho \geq 0$ local complementarity
- $b > 0$ global substitutability
- d_i = number of collaborators

- Potential function

$$\Phi(q, G) = \sum_{i=1}^n (\eta_i q_i - \nu q_i^2) - \frac{b}{2} \sum_i \sum_{j \neq i} q_i q_j + \frac{\rho}{2} \sum_i \sum_j a_{ij} q_i q_j - \zeta m$$

is such that

- $\Phi(q, G \oplus (i, j)) - \Phi(q, G) = \pi_i(q, G \oplus (i, j)) - \pi_i(q, G)$
- $\Phi(q'_i, q_{-i}, G) - \Phi(q, G) = \pi_i(q'_i, q_{-i}, G) - \pi_i(q, G)$

2 Link formation, arrival rate τ , (i, j) choose whether to link

$$P(\omega_{t+\Delta t} = (q_t, G_t \oplus (i, j)) | \omega_t = (q_t, G_t)) = \tau \frac{e^{\delta \Phi(q, G_t \oplus (i, j))}}{e^{\delta \phi(q, G_t \oplus (i, j))} + e^{\delta \phi(q, G_t)}} \Delta t$$

- Linking if $\pi_i(q, G_t \oplus (i, j)) - \pi_i(q, G_t) + \epsilon_{i,j,t} > 0$ and $\pi_j(q, G_t \oplus (i, j)) - \pi_j(q, G_t) + \epsilon_{i,j,t} > 0$
- Difference in π equal for i and j , and $= \Phi(q, G \oplus (i, j)) - \Phi(q, G)$

Network formation process 3

- 3 Link removal, arrival rate ξ , (i, j) choose whether to remove link

$$P(\omega_{t+\Delta t} = (q_t, G_t \ominus (i, j)) | \omega_t = (q_t, G_t)) = \xi \frac{e^{\vartheta \Phi(q, G_t \ominus (i, j))}}{e^{\vartheta \Phi(q, G_t \ominus (i, j))} + e^{\vartheta \Phi(q, G_t)}} \Delta$$

- Model is continuous time, discrete state Markov chain
- Stationary distribution:

$$\mu^\vartheta(q, G) = \frac{e^{\vartheta(\Phi(q, G) - m \log(\xi/\tau))}}{\sum_{G' \in \mathcal{G}^n} \int_{Q^n} e^{\vartheta(\Phi(q, G') - m' \log(\xi/\tau))} dq'}$$

where

- Potential function

$$\Phi(q, G) = \sum_{i=1}^n (\eta_i q_i - \nu q_i^2) - \frac{b}{2} \sum_i \sum_{j \neq i} q_i q_j + \frac{\rho}{2} \sum_i \sum_j a_{ij} q_i q_j - \zeta m$$

is such that

- $\Phi(q, G \oplus (i, j)) - \Phi(q, G) = \pi_i(q, G \oplus (i, j)) - \pi_i(q, G)$
- $\Phi(q'_i, q_{-i}, G) - \Phi(q, G) = \pi_i(q'_i, q_{-i}, G) - \pi_i(q, G)$
- Propositions 2-3 characterize stationary distribution

Figure 1: The average degree \bar{d} (left panel) and the average output \bar{q} (right panel) as a function of the linking cost ζ for varying values of $\theta \in \{0.05, 0.1, 0.2\}$ with $n = 20$ firms and $\tau = \xi = \chi = 1$, $\eta = 300$, $\rho = 1$, $b = 1$ and $\nu = 20$. Dashed lines indicate the theoretical predictions of Equations (10) and Equation (12) in Proposition 2, respectively.

Note: The logarithm of a firm's R&D expenditures (by thousand dollars) measures its R&D effort. A Firm's productivity is measured by the ratio of sales to employment. The logarithm of the number of patents is used as a control variable in the linking cost function [cf. e.g. [Hanaki et al., 2010](#)].

^a Market share in the primary 3-digit sector in which the firm is operating.

^b The relative welfare gain due to subsidizing the R&D collaboration costs between firms *i* and *j* is computed as $\Delta W = (E_{\mu, \sigma}[W(\mathbf{q}, G|\psi_{ij} = 0)] - W(\mathbf{q}^{\text{obs}}, G^{\text{obs}})) / W(\mathbf{q}^{\text{obs}}, G^{\text{obs}})$, where \mathbf{q}^{obs} and G^{obs} denote the observed R&D expenditures and network, respectively.

^c ΔW_F denotes the relative welfare loss due to a merger of firms assuming a fixed network of R&D collaborations.

Section 2

Atalay et al. (2011)

Atalay et al. (2011): Network structure of production

- Model of buyer-supplier network of US firms
- Common features of observed social & economic networks: (see Jackson (2010))
 - Scale-free: degree distribution is Pareto: $P(d) = cd^{-\gamma}$ i.e. $\log P(d)$ is linear function of $\log d$.
 - Small worlds: the diameter & average path length tends to be small even for a large number of nodes (e.g. 6 degrees of Kevin Bacon; Erdős number)

Preferential attachment 1

- Growing random network model that is scale-free and has small worlds
- Model: nodes born over time and indexed by date of birth
 - Begin with m nodes fully connected
 - Time t one node added and forms m connections with existing nodes, connects to node i with probability $\frac{d_i(t)}{\sum_j d_j(t)} = \frac{d_i(t)}{2tm}$

- Solving for degree distribution: “mean-field approximation”
 - $P(i \text{ gets new link}) = m \frac{d_i(t)}{2tm} = \frac{d_i(t)}{2t}$
 - Approximate time as continuous instead of discrete

$$\frac{d}{dt}d_i(t) = \frac{d_i(t)}{2t}$$

and $d_i(1) = m$, implies

$$d_i(t) = m \left(\frac{t}{i} \right)^{1/2}$$

- Degree of older nodes > degree of younger nodes, at time t node born at time $i = t \left(\frac{m}{d} \right)^2$ has degree d , so
 $F_t(d) = 1 - m^2 d^{-2}$, $P_t(d) = m^2 d^{-3}$

Observed degree distribution

network
formation

References

- Notation:
 - $N(t)$ firms at time t
 - $n(k, t)$ firms with in-degree k at time t
 - $m(t) = \frac{\sum_k kn(k, t)}{N(t)}$ average in-degree
- Each period:
 - ① Exit: each firm exists with probability q ; destroys $q(2 - q)N(t)m(t)$ edges, $q(1 - q)N(t)m(t)$ of which have receiving vertex survive
 - ② Reconnection: surviving firms whose connections were lost due to exit reconnect; $q(1 - q)N(t)m(t)$ reconnections to make
 - r uniformly at random
 - $1 - r$ by preferential attachment
 - ③ Entry:
- $(g + q)N(t)$ firms enter, each form $m(t)$ edges
 - $\delta(1 - r)$ by preferential attachment to existing firms
 - $r\delta$ randomly to existing firms
 - $1 - \delta$ randomly to other entrants

Hsieh, König,
and Liu (2024)Atalay et al.
(2011)

References

$$\frac{\partial}{\partial t} n(k, t) + \frac{\partial}{\partial k} [n(k, t) \gamma(k, t)] = \beta(k, t) N(t) (q + g) - q n(k, t)$$

- $\gamma(k, t)$ = in-degree growth rate
 - $= \frac{dk}{dt} = qr(m(t) - k) + \frac{\delta(k + r(m(t) - k))(q + g)}{1 - q}$
- $\beta(k, t)$ = in-degree distribution of entering vertices
 - = binomial $\left((g + q)N(t)(1 - \delta)m(t), \frac{1}{N(t)(g + q)} \right)$
 - $\approx \frac{1}{m(t)(1 - \delta)} e^{-\frac{k}{m(t)(1 - \delta)}}$ (exponential)
- Let $p(k, t) = \frac{n(k, t)}{N(t)}$,

$$\frac{\partial p(k, t)}{\partial t} + \frac{\partial}{\partial k} [p(k, t) \gamma(k, t)] = \beta(k, t) (q + g) - qp(k, t)$$

Mean-field approximation 2

- Solve for steady-state degree distribution, $p(k)$

$$\frac{\partial}{\partial k} [p(k)\gamma] = \beta(k)(q + g) - qp(k)$$

so

$$p(k) = \lambda(k + R)^{-1-S} (\Gamma[1 + S, R/(m(1 - \delta))] - \Gamma[1 + S, (R + k)])$$

where R , S and λ are functions of δ , q , g , m , and r

References

- Sequential: N nodes, T periods
- Begin with no links
- Each period two nodes meet and have opportunity to form a link
- Payoff of i from linking with j at time t

$$U_i(j | \underbrace{X}_{\text{Node characteristics}}, \underbrace{C}_{\text{link characteristics}}, G_{t-1}, t)$$

- Link formed if

$$g(U_i(j|X, C, G_{t-1}, t), U_j(i|X, C, G_{t-1}, t)) > 0$$

- Myopic behavior:

$$U_i(j|X, C, G_{t-1}, t) = U_i(j|X, C, G_{t-1})$$

- Individuals do not have to take expectation over future links
- Avoids multiple equilibria & computational difficulties

- Preferences:

$$U_i(j|X, C, G_{t-1}) = \beta_0 + \beta'_1 x_j - (x_i - x_j)' \Omega (x_i - x_j) + \\ + \alpha_1 d_{jt} + \alpha_2 d_{jt}^2 + \alpha_3 d(i, j; G_{t-1}) + \delta c_{ij} + \epsilon_{ij}$$

Non-transferable:

$$g(u_i, u_j) = \mathbf{1}\{u_i \geq 0 \ \& \ u_j \geq 0\}$$

- $\epsilon_{ij} \sim \text{logistic, independent}$
- Sequence of meetings, M : assume $T = N(N-1)/2$, each potential pair meets exactly once, all sequences equally likely
- Parameter meanings:
 - β individual characteristics
 - Ω captures homophily
 - α network characteristics
 - δ pair characteristics

- Bayesian
- Likelihood

$$\mathcal{L}(\theta|G, X, C) = P(G|X, C; \theta) = \sum_{M \in \mathbb{M}} P(M|X, C; \theta) P(G|M, X, C; \theta)$$

- $P(G|M, X, C; \theta)$ is product of logit probabilities
- $|\mathbb{M}| = (N(N-1)/2)!$ is too large for MLE
- Compute posterior using MCMC — Metropolis-Hastings with data augmentation
 - Draw $\theta_k|M_k$ from $P(\theta|M_k, G, X, C) \propto P(G|M_k, X, C, \theta)P(\theta)$
 - Draw $M_{k+1}|\theta_k$ from $P(M|\theta_k, G, X, C) \propto P(G|M_k, X, C, \theta)P(M)$
- Data from a single large network
 - Properties of estimator as $N \rightarrow \infty$ unknown
 - [Chandrasekhar and Jackson \(2013\)](#), [Leung \(2013\)](#) also have data from a single network and show consistency of their estimators (but models differ)

Chandrasekhar and Jackson (2013)

- Consistent and tractable network formation model
- Setup nests variant of [Christakis et al. \(2010\)](#) model
- Starting point: exponential random graph (ERGM):

- Network $g \in G$
- Vector of statistics $S(g)$
- Likelihood:

$$P_{\theta}(g) = \frac{e^{\theta S(g)}}{\sum_{g' \in G} e^{\theta S(g')}}$$

- Broad class, can represent any random graph model
- Used in many applications
- Challenges of ERGMs: set of networks, G very large, typically estimated by MCMC, but consistency unknown and mixing time exponential in number of nodes
- This paper: propose a related class of models, give conditions for consistent and asymptotically normal estimation, give examples of strategic network formation models that fit into setup

- Statistical exponential random graph model
- Write model on space of statistic instead of network

$$P_{\beta, K}(s) = \frac{K(s)e^{\beta s}}{\sum_{s' \in A} K(s')e^{\beta s'}}$$

- Estimate β by MLE or GMM
- Sum in denominator is over space of statistic instead of possible networks
- Sufficient conditions for consistent, asymptotically normal $\hat{\beta}$ (loosely):
 - Statistics are counts, e.g. of links, triangles, stars, etc
 - Graph is not too dense

- Subgraph generation models
- List of subgraph types G_ℓ^n , $\ell = 1, \dots, k$
- Probabilities p_ℓ^n of each type
- Formation:
 - Each subnetwork in G_1^n formed with probability p_1^n
 - Repeat for $\ell = 2, \dots, n$
- E.g. Erdos-Renyi: $G_1^n =$ all pairs of nodes
- \hat{p}_ℓ^n consistent and asymptotically normal if network is sparse

Strategic network formation as SUGM

- If payoff depends only on subgraph, then natural
- I.e. if $u_i(g)$ only depends on direct connection or direct connections + friends of friends etc
- E.g. in [Christakis et al. \(2010\)](#)

$$\begin{aligned}
 U_i(j|X, C, G) = & \beta_0 + \beta_1' x_j - (x_i - x_j)' \Omega (x_i - x_j) + \\
 & + \alpha_1 d_j + \alpha_2 d_j^2 + \delta c_{ij} + \\
 & + \alpha_3 1\{d(i, j; G) = 2\} + \alpha_4 1\{d(i, j; G) = 3\} + \epsilon_{ij}
 \end{aligned}$$

References

- Infinite horizon, discrete time
- Network $g \in G$
- Contracts (payments) $t_g = \{t_{ij;g}\}_{ij \in g}$
- Per-period payoffs: $\pi_i(g, t_g)$

Model: each period

- Start with network $g^{\tau-1}$
- ① Network formation:
 - ① Simultaneously announce links a_i that want to negotiate, private payoff shock $\epsilon_{a_i,i}$ received
 - ② Network of negotiations: $\tilde{g}(a)$
 - If i & j both announced link, $ij \in \tilde{g}(a)$,
 - Everyone pays cost $c_i(\tilde{g}(a)|g^{\tau-1})$

Model: each period

- Start with network $g^{\tau-1}$
- ① Network formation:
 - ① Simultaneously announce links a_i that want to negotiate, private payoff shock $\epsilon_{a_i,i}$ received
 - ② Network of negotiations: $\tilde{g}(a)$
 - If i & j both announced link, $ij \in \tilde{g}(a)$,
 - Everyone pays cost $c_i(\tilde{g}(a)|g^{\tau-1})$
- ② Bargaining:
 - ① Additive payoff shocks η_{ij} observed
 - ② Unstable links $ij \in \tilde{g}$ with no gains from trade (given rest of network) dissolves, repeat until no such pairs remain to get $g^\tau \subseteq \tilde{g}$
 - ③ Contracts t_g^τ determined by Nash bargaining, payoffs realized

$$\bar{\pi}_i(g^\tau, \eta, t_g^\tau) = \pi_i(g^\tau, t_g^\tau) + \sum_{ij \in g^\tau} \eta_{ij}$$

Model - dynamics

- Markov strategies $\sigma_i(g, \epsilon_i)$
- Conditional choice probabilities

$$P_i^\sigma(a|g) = \int \mathbf{1}\{\sigma_i(g, \epsilon_i) = a\} f(\epsilon_i) d\epsilon_i$$
- $\Gamma(g; \eta, v^\sigma) = \text{subnetwork } g' \subseteq g \text{ such that all pairs stable}$
- Negotiation network probabilities

$$q_i^\sigma(g'|a_i, g) = \sum_{a_{-i}} \prod_{j \neq i} P_j^\sigma(a_j|g) \mathbf{1}\{\tilde{g}(a) = g'\}$$

- Choice-specific value function

$$v_i^\sigma(a, g) = \sum_{g'} q_i^\sigma(g'|a, g) (c_i(g'|g) + E_\eta [\bar{\pi}_i(g'', \eta, t_{g''}^\sigma) + \beta v_i^\sigma(g'') : \\ : g'' = \Gamma(g; \eta, v^\sigma)])$$

- Value function

$$v_i^\sigma(g) = \int \left(\max_a \epsilon_{a,i} + v_i^\sigma(a_i, g) \right) f(\epsilon_i) d\epsilon_i$$

Chandrasekhar and
Jackson (2013)

Lee and Fong (2013)

References

- Nash bargaining:
 - Surplus of i from trading with j

$$\Delta S_{i,j}^{\sigma}(g; \eta, \{t, t_{-ij:g}^{\sigma}\}) = (\bar{\pi}_i(g, \eta, \{t, t_{-ij:g}\}) + V_i^{\sigma}(g)) - \\ - (\bar{\pi}_i(g - ij, \eta, t_{-ij:g}) + V_i^{\sigma}(g - ij))$$

- Assumes if ij do not link, other links unaffected today (but they could be in the future)

$$t_{ij:g}(\eta) \in \arg \max_{\tilde{t}} \Delta S_{i,j}^{\sigma}(g; \eta, \{\tilde{t}, t_{-ij:g}^{\sigma}\})^{b_{ij}} \Delta S_{j,i}^{\sigma}(g; \eta, \{\tilde{t}, t_{-ij:g}^{\sigma}\})^{b_{ji}}$$

- Equilibrium existence from Brouwer's fixed point theorem
- Equilibrium may not be unique

Example

Figure 1: Potential Networks g_0, g_1, g_2, g_3 between firms U_1, D_1, D_2 . Period payoffs contained within circles; $t_{ij}(g_k)$ represents payment between U_i and D_j under network g_k .

- Contracting externalities
- Static model (or equivalently $\beta = 0$) with equal bargaining power
 - $t_{1,j}(g_2) = 6, t_{1,j}(g_3) = 4$
- Dynamic model with $\beta = 0.9, c() = 1, \text{var}(\epsilon) = \pi^2/8$
 - $t_{1,j}(g_2) \approx 7.6, t_{1,j}(g_3) = 4.4$
 - Chance of downstream firms being unlinked for multiple periods lowers value of their outside option
 - Distribution of states $[g_0, g_1, g_2, g_3] \approx [.00, .43, .43, .14]$, $P(g_1|g_2) = P(g_2|g_2) \approx 0.8$

- Much like dynamic games
- Approaches:
 - Constrained MLE: maximize pseudo-likelihood subject to equilibrium constraints
 - Two-step:
 - 1 Estimate policy functions: using Hotz-Miller inversion (e.g. with type I extreme value shocks)

$$\hat{\sigma}_i(g, \epsilon) = \arg \max_a \log(\hat{P}_i(a|g)) + \epsilon$$

- 2 Let $\tilde{\sigma}_i(\cdot; \theta)$ be the best response of player i when payoff parameters are θ and other players play $\hat{\sigma}_{-i}$, estimate θ to minimize

$$\hat{\theta} = \arg \min_{a, g, i} \sum \left(p_i^{\tilde{\sigma}_i; \hat{\sigma}_{-i}}(a|g) - p_i^{\hat{\sigma}}(a|g) \right)^2$$

Chandrasekhar and
Jackson (2013)

Lee and Fong (2013)

References

- “Intuitively, if there are gains from trade between two agents who form a link (given the actions of others), a static model would predict that the link should form regardless of which agent obtains a larger share. However, in a dynamic model, different values of Nash bargaining parameters will change each agent’s respective outside options through their continuation values, and hence only certain parameter values will be consistent with a link forming in equilibrium.”
- What data is observed?
 - Realized sequence of networks?
 - Sequence of networks + actions = announcements (i.e. we see potential links where negotiations failed)
 - 2-step estimator assumes the announcements observed, single step estimator allows only networks to be observed
 - Section 4.2 about estimation of bargaining parameter assumes (N, G, π, β, f, c) either observed, assumed, or can be separately estimated

Identification if π , c not known 1

- Assuming announcements observed, usual dynamic decision model identifies per-period payoff:

$$\tilde{\pi}(a|g) = \sum_{g'} q^P(g'|a, g) \left(c_i(g'|g) + E_{\eta}[\pi_i(\Gamma(g', \eta), t_{\Gamma(g', \eta)}^P, \eta)] \right)$$

- $q^P(g'|a_i, g)$ is known, so variation in a_i identifies

$$c_i(g'|g) + E_{\eta}[\pi_i(\Gamma(g', \eta), t_{\Gamma(g', \eta)}^P, \eta)]$$

- Need restriction to separate c_i and π_i , e.g. assume $c_i(g'|g) = 0$ if $g' = g$
- $\Gamma(g', \eta) = \text{stable subnetwork of } g'$

$$\Gamma(g, \eta) = \begin{cases} g \\ \Gamma(g', \eta) \text{ otherwise where } g' = g \setminus \{ij \in g : \Delta S_{ij}(G, \eta, t) > 0\} \end{cases}$$

- Need to untangle Γ , η , and π from bargaining
- Estimator assumes η degenerate

Example: Insurer-Provider negotiations

| | HMOs | 0.25 | 0.71 | 0.02 | 0.87 | 1.00 | 0.00 | 0.00 | 1.00 |
| (iv) Static, $+\Delta\pi^H \geq 0$ | Equal | - | - | 0.17 | 0.25 | 1.00 | 0.00 | 0.00 | 1.00 |
| | Hospitals | - | - | 0.25 | 0.50 | 1.00 | 0.00 | 0.00 | 1.00 |
| | HMOs | - | - | 0.08 | 0.52 | 1.00 | 0.00 | 0.00 | 1.00 |

Summary statistics from merger simulations, where: (i) and (ii) are from a dynamic model ($\beta = .9$), (iii) and (iv) from a static model, and (ii) and (iv) condition also on markets where hospitals find it profitable to merge. "B-Pow": Equal - $b_{ij} = .5 \forall ij$; Hospitals - $b_{ij} = .8$ when i is a hospital, .2 otherwise; HMOs - $b_{ij} = .8$ when i is an HMO, .2 otherwise. $+\Delta\pi^H, -\Delta\pi_{5\%}^H$: percentage of markets in which total hospital profits increases at all or falls by 5%; $+\Delta\pi^M, -\Delta\pi_{5\%}^M$: percentage of markets in which total HMO profits increases at all or falls by 5%; $+p^M, -p_{5\%}^M$: percentage of markets in which both HMO premiums increase or fall by 5%; $+Ins, -Ins_{5\%}$: percentage of markets in which total patients insured increases at all or falls by 5%.
